**092390 MULTICRITERION STORMWATER MANAGEMENT METHODS.** While detention basins designed to control peak discharge are effective in controlling peak rates, the basins are ineffective in controlling the degradation of erodible channels downstream of the basin. A relationship for making planning estimates of the volume of detention storage required to control channel erosion is provided. A procedure that can be used for design is also provided. Planning and design methods for water quality control through detention time control are also provided. The importance of adopting multicriterion stormwater management policies is emphasized, with the policy recommending control of flooding, channel erosion, and detention time for water quality enhancement. (Edited author abstract) 11 refs.

**092391 EFFECTIVENESS OF AN URBAN RUN-OFF DETENTION POND-WETLANDS SYSTEM.** The effectiveness of an urban detention system, composed of a detention pond and wetlands in series, in reducing constituent loads carried in runoff was determined. The detention pond was effective in reducing loads of suspended solids and suspended metals. Nutrient efficiencies were variable, ranging for all species and phases, from less than 0 to 72 percent. The wetlands generally was effective in reducing both suspended and dissolved loads of solids and metals. The system, by combining the treatment of the pond and wetlands, was very effective in reducing loads of most constituents. (Edited author abstract). 11 Refs.

**092392 ALTERNATIVE STRATEGIES FOR STORMWATER DETENTION.** In a simulation experiment, stormwater flows are partially diverted, at various levels, to a detention basin in order to compare the recombined (i.e., undiverted flows and basin discharges) hydrograph to the response of the traditional, in-line design. The use of off-line detention basins is shown to be an effective technique for reducing peak flows from developed watersheds to pre-development levels with lower storage requirements. In addition, the discharge hydrographs produced by off-line detention are significantly different from those produced by the traditional design and may be more suited to certain stormwater management situations. (Author abstract). 14 Refs.

## Estimation

**092393 ESTIMATING RUNOFF VOLUMES FROM FLAT, HIGH-WATER-TABLE WATERSHEDS.** Four methods of estimating stormwater runoff total volume are evaluated as to their performance on watersheds of Florida's flatwoods resource area. Three additional techniques representing modifications and extensions of existing methods are developed and their performance evaluated. Characteristics of flatwoods watersheds include extremely flat relief, sandy soils, dynamic shallow water tables, and scattered wetlands. Data collected by the U.S. Geological Survey (USGS) and South

Florida Water Management District (SFWMD) from the five small (8-1450 ha) agricultural watersheds (improved and unimproved pasture) served as the basis of evaluation. All total volume estimation techniques examined rely upon the SCS (Soil Conservation Service) runoff equation. Best results were achieved with methods which included antecedent depth to the water table as a measure of watershed storage potential. (Author abstract) 15 refs.

Capece, J.C. (Univ of Florida, Gainesville, FL, USA); Campbell, K.L.; Baldwin, L.B.; Konyha, K.D. *Trans ASAE* v 30 n 5 Sep-Oct 1987 p 1397-1402.

**092394 DETERMINISTIC APPROACH TO INFLOW DESIGN RAINFLOOD DEVELOPMENT AS APPLIED BY THE U.S. BUREAU OF RECLAMATION.** A brief introductory discussion is provided relative to the historical development of the deterministic approach used in the analysis of extraordinary flood events, namely the probable maximum flood, by the Bureau of Reclamation. The paper then proceeds from the brief historical treatment to a more detailed discussion emphasizing the current hydraulically based adaptation of the traditional unit hydrograph approach for modeling the conversion of rainfall to runoff. Among the properties identified and discussed are the geometric configuration of the drainage network as developed by geological processes and the hydraulic characteristics of the drainage network in terms of the system's hydraulic efficiency in conveying extreme magnitude flood discharges to points of runoff concentration. The generation of unit hydrographs for ungaged basins using the approach is discussed in some detail. Additional aspects of the subject are discussed. (Edited author abstract) 13 refs.

**092395 ESTIMATING RUNOFF PEAK RATES FROM FLAT, HIGH-WATER-TABLE WATERSHEDS.** Six methods of estimating stormwater runoff peak discharge are evaluated as to their performance on watersheds of Florida's flatwoods resource area. Characteristics of flatwoods watersheds include extremely flat relief, sandy soils, dynamic shallow water tables, and scattered wetlands. Data collected by the U.S. Geological Survey and South Florida Water Management District from five small (8 to 1450 ha) agricultural watersheds (improved and unimproved pasture) served as the basis of evaluation. Runoff peak rate estimation techniques ranged in approach from empirical formulas to an overland flow simulation model. Among the established methods examined, best results were achieved using the overland flow technique. Three of the six peak rate estimation methods (the SCS graphical method, the CREAMS hydrologic model equation, and the SCS triangular hydrograph method) were modified to improve their performance on flatwoods watersheds. (Author abstract) 18 refs.

**092396 FRACTALS AND THE RIVER-LENGTH CATCHMENT-AREA RATIO.** The fractal nature of stream-length and catchment-area measurement is investigated using eight rivers in Missouri. The fractal dimension for the length measurement was found to average 1.158 and for area to average 1.0105. These values are close to those hypothesized by Mandelbrot (1983). (Author abstract) 6 refs.

**092397 METODO PER LA STIMA DELLE PORTATE AL COLMO DI BACINI ITALIANI CON AREA MINORE DI 100 KM<sup>2</sup> ATTRAVERSO LE PORTATE GIORNALIERE.** [Method, Based on Daily Discharges, for Estimating the Peak Discharge of Italian Basins with an Area not Exceeding 100 km<sup>2</sup>.] Considering the ratio  $\lambda$  between the yearly maxima of peak

discharge  $Q$  and daily discharge  $q$  as a random variable, two formulae are given, by means of which the mean and standard deviation of  $\lambda$  can be derived from some geomorphological and hydrological characteristics of the basin. A method, based on these formulae, is also given to estimate the peak discharge with an assigned return period  $T$  from the yearly maxima of the daily discharge. The results, obtained from an analysis carried out on 72 Italian basins, are proposed for basins with an area not exceeding 100 km<sup>2</sup>. (Author abstract). 9 Refs. In Italian.

**092398 SIMPLE MODEL FOR RUNOFF ESTIMATION.** A simple model for runoff estimation is presented, with particular reference to Athens basin. The method is based on assumptions of a symmetrical exponential storm profile and a linear cumulative area - time relation, while a power law is postulated for correlating the storm peak factor with rainfall duration. A general expression is derived for the peak flow and discussed in comparison with the rational formula. Further, the outflow hydrograph from subcatchments of uniform characteristics is approximated by a triangular form. The model parameters for the Athens area are estimated from local rainfall data. Specific applications in Athens basin indicate good agreement with results of established techniques or observations, implying that the present method may constitute a useful tool in design practice. (Author abstract). 6 Refs.

Christodoulou, G.C. (Nat'l Technical Univ of Athens, Greece); Memos, C.D. *Int J Water Resour Dev* v 3 n 3 Sep 1987 p 207-215.

**092399 JOINT PROBABILITY ESTIMATES OF RETURN PERIOD FLOWS.** A methodology for combining rainfall probabilities and the probabilities of various antecedent conditions for estimating return period flows is presented. The methodology is based on the principles of derived distributions to combine the probability distributions of rainfall and runoff equation parameters to derive the distribution of flow. To date the majority of the authors' work has used the Extreme Value Type I distribution to describe rainfall probabilities and the lognormal distribution to describe the probability distribution of  $S$  in the SCS runoff equation. The method is not dependent on the form of the parent distributions that are used. Results from applying the method to watersheds near Stillwater, OK; Coshocot, OH; Hastings, NE; and Safford, AZ are presented. (Edited author abstract). 12 refs.

## Hydrology

**092400 PROJECTION OF URBANIZATION EFFECTS ON RUNOFF USING CLARK INSTANTANEOUS UNIT HYDROGRAPH PARAMETERS.** In order to predict flood conditions in 1990 for the Beargrass Creek watershed, Louisville, Kentucky, trends in the Clark Instantaneous Unit Hydrograph (Clark IUH) parameters were utilized to determine the 1990 unit hydrograph and flood conditions. Based on the results from this flood study, this paper demonstrates the applicability of using projected Clark IUH parameters for modeling future runoff conditions in an urbanizing watershed. Values of these parameters, as estimated from maximum annual historical flood data, are used to develop regression models for predicting future Clark IUH parameters. Using the projected parameters, selected annual flood events since 1973 are simulated in order to verify the accuracy of these projections. (Edited author abstract) 12 refs.

**092401 RECURSIVE ESTIMATION OF KERNELS OF NONLINEAR RAINFALL-RUNOFF MODELS.** Two algorithms, one for estimating the kernels of nonlinear functional series models of the rainfall-runoff process using a fixed length of rainfall-runoff data, and the other for updating the kernel estimates as additional data become available are proposed. These recursive algorithms are based on the steepest gradient method and are useful for on-line prediction of runoff. The estimation schemes are applied to model the daily rainfall-runoff process in the Rough river basin in Kentucky and the prediction results of both the linear and nonlinear models are compared. Improvement in prediction results brought about by fitting ARMA type models to residual sequences is discussed. (Author abstract) 19 refs.

**092402 ON HYDROLOGIC SIMILARITY: 2. A SCALED MODEL OF STORM RUNOFF PRODUCTION.** The paper describes a simple physically based conceptual model of runoff production based on catchment topography and the spatial variability of rainfall and soil properties. Both infiltration excess and saturation excess runoff production mechanisms are considered. The interaction between the two mechanisms of runoff production and the effect of a finite water table on the infiltration excess mechanism are explicitly considered. Dimensionless formulation has led to the identification of five similarity parameters and three dimensionless variables representing initial conditions and storm characteristics. Finally, a number of experiments were performed to study the sensitivity of the runoff production response to some of these similarity parameters. (Edited author abstract) 21 refs.

**092403 ANALYSIS OF OBJECTIVE FUNCTIONS USED IN URBAN RUNOFF MODELS.** The objective functions used in parameter estimation in urban runoff models are compared by using a method proposed by M.H. Diskin and E. A. Simon and the urban runoff model ILLUDAS. Two sets of objective functions, the first one used by Diskin and Simon in their study and a second one which includes other objective functions are used. Rainfall-runoff data from urban watersheds in the US are used in the study. The results indicate that the least squares criterion is the best among those studied. (Author abstract) 21 refs.

Rao, A. Ramachandra (Purdue Univ, West Lafayette, IN, USA); Han, Ji. *Adv Water Resour* v 10 n 4 Dec 1987 p 205-211.

**092404 DETERMINATION OF RUNOFF FREQUENCIES FOR UNGAUGED URBAN CATCHMENTS.** A method is described for generating flood frequency information for a catchment for a design situation. The technique comprises a combination of deterministic and stochastic components. This involves deterministically modelling the response of the catchment together with the use of a stochastic element to derive the conditional probability vector of the outlet hydrograph peaks. The advantage of the method is that the infiltration is modelled using a range of values that is described statistically. (Author abstract) 25 refs.

Lambourne, J.J. (Univ of the Witwatersrand, S Afr). *Water SA* v 14 n 1 Jan 1988 p 1-6.

**092405 MODELING PHOSPHORUS TRANSPORT IN SURFACE RUNOFF.** A submodel for esti-

imating phosphorus loss from agricultural watersheds has been developed and incorporated into the ANSWERS watershed model. Model validation was accomplished using data from field plots. The model's usefulness as a planning tool was demonstrated on a watershed in Virginia. The model uses ANSWER's extended sediment transport option to describe the transport of individual particle size classes. A nonequilibrium desorption equation is used to account for the desorption of phosphorus from the soil to surface runoff. Sediment-bound phosphorus is modeled as a function of the specific surface area of the soil and sediment. The equilibrium between soluble and sediment-bound phosphorus is modeled using a Langmuir isotherm. (Author abstract) 41 refs.

**092406 MODIFIED CREAMS NUTRIENT MODEL FOR COASTAL PLAIN WATERSHEDS.** In evaluating the suitability of the CREAMS model for simulating nutrient yield from Coastal Plain — flatwoods — watersheds in South Florida, it was determined that assumptions made in developing the model were not valid for the sandy soils prevalent in this region. Conceptual changes to the model led to the development of the CREAMS-WT version which better represents the low phosphorus buffering capacity of these sandy soils. For verification, two watersheds were simulated without calibration: a beef pasture with low nutrient loading, and a dairy watershed with very high nutrient loading. Predicted annual flow-weighted concentrations of total-N and total-P compare closely with observed values for both sites, correctly reflecting the response of these extreme cases of nutrient loading. A sensitivity analysis of new and modified parameters is presented along with comments on estimating parameters. (Author abstract) 20 refs.

**092407 STORAGE-EFFECTIVE DRAINAGE (SED) RUNOFF MODEL.** The storage-effective drainage (SED) runoff model was developed to assist in the research objectives of Alberta Environment's Spring Creek Experimental Watershed Project. The project's primary mandate was to identify the effects of large scale deforestation in a pristine boreal forest on the hydrologic cycle. During the research pretreatment phase it was observed that: (1) during two consecutive water years the basin had a 50% difference in annual input but displayed a 700% difference in annual output; and (2) two storms, with the same magnitude and intensity, generated output responses that differed by a multiple of 500. Recognizing the wide range of watershed responses to a given input it is impossible to distinguish the effects of deforestation using the established investigative tools of regression and statistical analyses particularly when dealing with small data samples. For this reason the SED model, which uses changes in basin storage conditions as a means of accurate runoff modelling and hydrograph reconstitution, was developed. (Author abstract) 2 refs.

**092408 RATIONAL FORMULA INTERPRETED USING A PHYSICALLY-BASED MATHEMATICAL MODEL.** A new interpretation is given for the rational formula in view of a mathematical model founded on the kinematic overland flow and Green and Ampt infiltration equations. The potential variability of the runoff coefficient with various rainfall and basin characteristics is demonstrated. However, using the concept of hydrologic similarity, it is possible to predict the runoff coefficient in terms of several physically-based non dimensional parameters for homogeneous planar, rectangular basins. 1988 p 41-52.

**092409 WATERSHED RUNOFF MODELLING - A CASE STUDY.** In this paper an attempt has been made to study the interrelationships among some selected geomorphic parameters. The geomorphic parameters are further grouped into different characteristic groups and used for development of regression models for prediction of mean annual runoff. In all, about 24 models are developed and the best fit model is identified which can be conveniently used for prediction of runoff of an ungauged watershed in any region having similar physiographic features as that of Upper Damodar Valley. (Author abstract) 26 refs.

Misra, N. (IIT, Kharagpur, India). *J Inst Eng India Part AG* v 68 Jan 1988 p 91-95.

**092410 DETERMINATION OF THE SPRING RUNOFF FOR A BASIN WITH ABUNDANT LAKES USING A STEPWISE LINEAR STORAGE MODEL.** Humid regions contain areas in which the storage capacity of lakes is a very important factor in determining the yearly distribution of runoff. The purpose of this paper is to show first that a stepwise linear storage model may be used for estimating spring runoff, and second that runoff data from small lakeless basins can be used as input in a model for large basins with several lakes. The model has two parameters that must be determined by calibration. The first is associated with the number of sub-basins draining into the lakes, and the second indicates the time delay of snow melt in the larger basin as compared with that of the small basin. The model may be used for forecasting purposes and for estimating runoff in cases in which runoff data are lacking. (Edited author abstract) 10 refs.

Virta, Juhani (Dep of Geophysics, Helsinki, Finl). *Aqua Fenn* v 17 n 2 1987 p 115-121.

**092411 REGRESSION ESTIMATES FOR TOPOLOGICAL-HYDROGRAPH INPUT.** Physiographic, hydrologic, and rainfall data from 18 small drainage basins in semiarid, central Wyoming were used to calibrate topological, unit-hydrograph models for celerity, the average rate of travel of a flood wave through the basin. The data set consisted of basin characteristics and hydrologic data for the 18 basins and rainfall data for 68 storms. Calibrated values of celerity and peak discharges subsequently were regressed as a function of the basin characteristics and excess rainfall volume. Predicted values obtained in this way can be used as input for estimating hydrographs in ungauged basins. The regression models included ordinary least-squares and seemingly unrelated regression. This latter regression model jointly estimated the celerity and peak discharge. (Edited author abstract) 13 refs.

Karliringer, Michael R. (US Geological Survey, Denver, CO, USA); Guertin, D. Phillip; Troutman, Brent M. *J Water Resour Plann Manage* v 114 n 4 Jul 1988 p 446-456.

**092412 UNCERTAINTY ESTIMATES FOR SURFACE RUNOFF MODELS.** A lower bound for variance in surface runoff modelling estimates is advanced. The bound is derived using a linear unit hydrograph approach which utilizes a discretization of the catchment into an arbitrary number of subareas, a linear routing technique for channel flow effects, a variable effective rainfall distribution over the catchment, and calibration parameter distributions developed in correlating rainfall-runoff data by the model. The uncertainty bound reflects the dominating influence of the unknown rainfall distribution over the catchment and is expressed as a distribution function that can be reduced only by supplying additional rainfall-runoff data. It is recommended that this uncertainty distribution in modelling results be included in

flood control design studies in order to incorporate a prescribed level of confidence in flood protection facilities. (Author abstract). 8 Refs.

**092413 PROGRESS IN DEVELOPING AN OPERATIONAL SNOWMELT-RUNOFF FORECAST MODEL WITH REMOTE SENSING INPUT.** In order to apply to snowmelt-runoff model (SRM) or any snowmelt model operationally, a logical progression is required from utilization in the pure simulation mode when all data are known to the pure forecasting mode when no future data are known. Significant progress has been made and results are presented which include pure simulation, simulation when the actual output data are unknown, simulation when estimated or forecasted snow cover input data are employed, simulations or forecasts with updating using observed streamflow, and first attempts at true forecasts. Based on these results, an objective method for forecasting with SRM is being developed. (Author abstract). 10 Refs.

Rango, A. (USDA, Beltsville, MD, USA). *Nord Hydrol* v 19 n 2 1988 p 65-76.

**092414 DETERMINATION OF RUNOFF FREQUENCIES FOR UNGAUGED URBAN CATCHMENTS.** Engineers often intuitively use the recurrence interval of a design storm for runoff recurrence interval. It is suggested that this assumption is not soundly based, as the antecedent moisture content (AMC) or catchment wetness has a significant effect on the storm runoff recurrence interval. A method is described for generating flood frequency information for a catchment for a design situation. The technique comprises a combination of deterministic and stochastic components. This involves deterministically modelling the response of the catchment together with the use of a stochastic element to derive the conditional probability vector of the outlet hydrograph peaks. The advantage of the method is that the infiltration is modelled using a range of values that is described statistically. (Author abstract). 25 Refs.

Lambourne, J.J. (Univ of the Witwatersrand, Johannesburg, S Afr). *Water SA* v 14 n 1 Jan 1988 p 1-6.

**092415 RAINFALL-RUNOFF MODELING—PAST, PRESENT AND FUTURE.** A brief review of the historical development of mathematical methods used in rainfall-runoff modeling is presented. A simple classification of the current available models based upon both a priori knowledge and problem requirements is proposed in order to assess the state of the art. Finally an analysis of emerging problems in hydrology is used to ascertain possible future developments and trends. 51 Refs.

Todini, E. (Univ of Bologna, Italy). *J Hydrol* v 100 n 1-3 Jul 30 1988 p 341-352.

**092416 APPROXIMATE CONFIDENCE INTERVALS FOR VERIFICATION CRITERIA OF THE WMO INTERCOMPARISON OF SNOWMELT RUNOFF MODELS.** The comparison of the performances of hydrological models is usually based on the values of criteria which are functions of the differences between estimated and observed flows. In comparing models we have to consider whether the differences between performance criterion values may be due to sampling variation. To deal with this problem, the comparison of approximate confidence intervals of criterion values using the jackknife statistic is proposed. The method is applied to the results of the recent WMO project for the intercomparison of conceptual models of snowmelt runoff. (Author abstract). 21 Refs.

Cavadas, G. (McGill Univ, Montreal, Que, Can); Morin, G. *Hydrol Sci J* v 33 n 4 Aug 1988 p 369-377.

**092417 PROBLEMS OF RAINFALL-RUNOFF MODELLING IN ARID AND SEMIARID REGIONS.** The distinctive features of arid and semiarid regions affect rainfall-runoff modeling on both a discrete event basis and

a continuous basis. The general characteristics of arid zone hydrological processes and the problems they present in runoff modeling are discussed. Both sloping lands with integrated stream networks and flatlands with repetitive micro-hydrology are considered. The wide diversity in some characteristics may require different parameter values and possibly different approaches in different regions. Lack of observed data provides the major problem for runoff modeling in arid regions. Some comments are given on appropriate approaches to modeling for sloping regions. (Author abstract). 69 Refs.

Pilgrim, D.H. (Univ of New South Wales, Kensington, Aust); Chapman, T.G.; Doran, D.G. *Hydrol Sci J* v 33 n 4 Aug 1988 p 379-400.

**092418 MODALP: A DETERMINISTIC RAINFALL-RUNOFF MODEL FOR LARGE KARSTIC AREAS.** A model has been developed for fractured-fissured and karstic aquifers and it consists of two main systems, one of which represents the surface drainage area and simulates the peak flows of the hydrograph while the other simulates the inflows from the adjacent closed basins that contribute to the baseflow. Each of the two systems consists of two reservoirs. The first reservoir represents the soil cover and the unsaturated zone. Its main function is to deliver the effective precipitation to the second reservoir. The second reservoir represents the saturated zone of the karst system. Since the intensity of karstification decreases with depth, a variable discharge coefficient is considered in the model. The model has been applied successfully to the Manavgat River basin in Turkey, a highly karstified area. (Author abstract). 10 Refs.

Arikan, Alparslan (Hacettepe Univ, Ankara, Turk). *Hydrol Sci J* v 33 n 4 Aug 1988 p 401-414.

**092419 STOCHASTIC MODELLING OF RUNOFF FROM AN AGRICULTURAL WATERSHED IN SOUTHERN SASKATCHEWAN.** Analyses of hydrologic information collected from a small agricultural watershed near Swift Current in southern Saskatchewan from the past 35 yr revealed marked variations in the runoff behavior from year to year. Two simple stochastic models have been proposed, one for synthesizing monthly runoff flow and the other for snowmelt runoff simulation. Bayesian statistics have been utilized for estimating different conditional probabilities of runoff events for subunits within the watershed. When combined with historical runoff records, synthesized runoff flow may improve hydrologic design criteria for engineering structures. Frequency values of annual runoff and maximum one day runoff have also been computed on the basis of extreme value distribution. (Author abstract). 13 Refs.

**092420 QUANTITY OF STORMWATER RUNOFF FROM TEN STRETCHES OF ROAD, A CAR PARK AND EIGHT ROOFS IN HERTFORDSHIRE, ENGLAND DURING 1983.** Rainfall and runoff were monitored simultaneously for one year from a residential road, a car park, nine sections of road draining to individual gullies, two house roofs, two garage roofs, and three types of factory roof. The sites, included an automatic weather station in Redbourn, Hertfordshire. The percentage runoff averaged 11.4 per cent for roads and 56.9 per cent for roofs. Percentage runoff from the roads was cyclic with a peak during the summer months but there was a marked variation in monthly percentage runoff within and between sites. Regression analysis to explain percentage runoff was undertaken with various subsets of data for: each site; roads; and roofs. 'Seasonal' variables had a positive relationship for loads which shows that the percentage runoff from roads is higher in summer than winter. The antecedent variables showed that percentage runoff from roads and roofs is increased by antecedent

rainfall. Depression storage, assessed by examining rainfalls that did and did not produce runoff, showed a diversity of monthly values. Peak runoff from the results showed an attenuation to 12.8 per cent for 1 minute rainfall intensities and 24.2 per cent for 5 minute intensities. For roofs the attenuation averaged 36.8 per cent for 1 minute intensities and 92.6 for 5 minute intensities. Additional aspects of the study are discussed. (Edited author abstract). 3 Refs.

## Models

**092421 APPLICATION OF THE PRECIPITATION-RUNOFF MODEL IN THE WARRIOR COAL FIELD, ALABAMA.** A deterministic precipitation-runoff model, the Precipitation-Runoff Modeling System, was applied in two small basins located in the Warrior coal field, Alabama. Each basin has distinct geologic, hydrologic and land-use characteristics. Preliminary daily and storm calibrations were developed for each basin. Initial parameter and variable values were determined according to techniques recommended in the user's manual for the modeling system and through field reconnaissance. Parameters with meaningful sensitivity were identified and adjusted to match hydrograph shapes and to compute realistic water year budgets. When the developed calibrations were applied to data exclusive of the calibration period as a verification exercise, results were comparable to those for the calibration period. The model calibrations included preliminary parameter values for the various categories of geology and land use in each basin. The parameter values for areas underlain by the Pottsville Formation in the Bear Creek basin were transferred directly to similar areas in the Turkey Creek basin, and these parameter values were held constant throughout the model calibration. Parameter values for all geologic and land-use categories addressed in the two calibrations can probably be used in ungauged basins where similar conditions exist. The parameter transfer worked well, as a good calibration was obtained for Turkey Creek basin. (Edited author abstract) 41 refs.

**092423 TOWARD SNOWMELT RUNOFF FORECAST BASED ON MULTISENSOR REMOTE-SENSING INFORMATION.** Snow-cover mapping is a prerequisite for deriving the main input variable for a deterministic snowmelt runoff model (SRM). Operational forecasting of snowmelt runoff has to rely on guaranteed snow-cover information for a specific area and time. Remote sensing can provide the necessary data, especially when different sensor systems are available for combined interpretations. It has been shown already how

remote-sensing information from Landsat-MSS and NOAA-AVHRR supplement each other. It is important, though, that when using coarse spatial sensor resolution, special attention to the area, its topography, and the amount of snow coverage be taken. 7 refs.

## Sedimentation

**092424 CONCEPTUAL CATCHMENT MODEL FOR ESTIMATING SUSPENDED SEDIMENT FLOW.** A conceptual catchment model of the instantaneous unit sediment graph was developed for sediment graph prediction and to determine the effect of soil conservation measures on sediment flow for a mountainous watershed by routing mobilized sediment through a series of linear reservoirs. The sediment graphs generated by convolution of the instantaneous unit sediment graph with mobilized sediment were compared with the natural observed ones on the Chaukhutia watershed comprising an area of 452 km<sup>2</sup> of the Ramganga reservoir catchment. The mobilized sediment during a storm was related to rainfall excess and the parameters of the model were estimated utilizing fourteen sediment events observed during the years 1976-84. (Author abstract) 12 refs.

Kumar, Swantosh (G.B. Pant Univ of Agriculture & Technology, Pantnagar, India); Rastogi, R.A. *J Hydrol* v 95 n 1-2 Nov 15 1987 p 155-163.

**092425 SIZE DISTRIBUTION OF SEDIMENT AS AFFECTED BY SURFACE RESIDUE AND SLOPE LENGTH.** Runoff samples for determination of size distribution of sediment were collected under simulated rainfall conditions at selected downslope distances on plots covered with sorghum and soybean residue at rates ranging from 0.00 to 6.73 t/ha. The effects of surface residue and slope length on size distribution of sediment were evaluated. Substantial movement of sediment in the form of aggregates was found for each of the residue treatments. Significant differences in size distribution of sediment occurred between residue treatments. For a given residue rate, differences in sediment size distribution were found between sorghum and soybean residue. Size distribution of sediment was also determined to be significantly different at selected downslope distances. (Author abstract) 19 refs.

Gilley, J.E. (ISDA-ARS, Lincoln, NE, USA); Finkner, S.C.; Varvel, G.E. *Trans ASAE* v 30 n 5 Sep-Oct 1987 p 1419-1424.

**092426 SIZE AND SURFACE TEXTURE OF SEDIMENT IN AN URBAN CATCHMENT.** The size and surface texture of sediment collected in stormwater runoff from an urban catchment of 420 hectares in NW London were examined. The area comprised mixed urban land uses drained by a separate sewer system; seven land use classes were recognized as sediment sources. Sediment was examined using an electronic particle counter and scanning electron microscopy. A Fuzzy Classification Technique was used to analyze the micrographs. Sediment composition varied, but that reaching the sewer system was predominantly quartz particles, <100µm, and of abraded appearance. Early stages of silica precipitation on particles were noted. (Author abstract) 46 refs.

**Simulation** See WATERSHEDS—Sampling.

## Testing

**092427 SIMULATION OF SURFACE RUNOFF AND PIPE DISCHARGE FROM AN AGRICULTURAL SOIL IN NORTHERN SWEDEN.** In order to

test the ability of a physically based water and heat model to predict surface runoff and pipe discharge, adaptations were made to an agricultural field in the north of Sweden. A five-year period was selected, including observations of meteorological data, frost in the soil and discharge. Surface runoff was the dominating part of the total runoff, especially during conditions of frozen soil. The simulated discharge agreed well with the general partitioning between surface runoff and pipe discharge but discrepancies occurred in their temporal patterns. A probable explanation of these discrepancies was that the model did not account for the enhanced spatial heterogeneity in water flow through snow and in partially frozen soil. (Edited author abstract) 22 refs.

Jansson, Per-Erik (Swedish Univ of Agricultural Sciences, Uppsala, Swed); Gustafson, Arne. *Nord Hydrol* v 18 n 3 1987 p 151-166.

**092428 INFLUENCE OF TILLAGE SYSTEMS AND RESIDUE LEVELS ON RUNOFF, SEDIMENT, AND PHOSPHORUS LOSSES.** A rainfall simulator was used to study the effects of conventional tillage and no-till on the losses of runoff, sediment, and phosphorus (P) from agricultural lands. No-till was found to be effective in reducing runoff and sediment losses. Runoff and sediment losses decreased as residue level increased, regardless of the tillage system. Increasing crop residue level from 0 to 750 kg/ha caused a decrease in average orthophosphorus (PO<sub>4</sub>) concentration for both tillage systems. However, as the crop residue level increased, from 750 to 1,500 kg/ha, the PO<sub>4</sub> concentrations increased. Both PO<sub>4</sub> and total-P (P<sub>T</sub>) losses were greatest with the 0 kg/ha residue treatment, intermediate with 1,500 kg/ha residue, and least with 750 kg/ha residue. Additional study results are discussed. (Edited author abstract) 24 refs.

## Morphology

**092429 AN EXAFS STUDY ON THE MORPHOLOGY CHANGE OF Ru CATALYST BY CO ADSORPTION.** In this communication we present another example of the morphology change upon adsorption for Ru supported on γ-O<sub>2</sub> and show this phenomenon is not limited to Rh. The following conclusions can be drawn from the present study. First, ultradispersed Ru clusters are formed on alumina support from Ru<sub>3</sub>(CO)<sub>12</sub>. Second, Ru-Ru bonds in the very tiny Ru clusters are disrupted by CO adsorption, leading to the formation of a new species like Ru(CO)<sub>n</sub>. Third, the tiny Ru clusters are recovered by CO desorption. 12 refs.

## Spectroscopic Analysis

**092430 LUMINESCENCE DECAY CHARACTERISTICS OF Ru(bpy)<sub>3</sub><sup>2+</sup> IN DILUTE SINGLE CRYSTALS AND POLYMER HOSTS.** Luminescence decay characteristics for Ru(bpy)<sub>3</sub> doped in dilute single-crystals and polymer hosts have been measured in the temperature range 1.5 to 77 K using 1 ms square-pulse excitation from an acousto-optically modulated Ar<sup>PLU</sup> laser. Previously observed deviations from single-exponential decay behavior in experiments using higher-power, short (3 ns) pulse excitation, are shown to be mainly due to sample heating effects. The temperature dependence of the decay times is

consistent with luminescence from three states of equal degeneracy, separated by (8±0.5) and (60±5) cm<sup>-1</sup> respectively. (Author abstract). 22 Refs.

Krausz, Elmar (Australian Natl Univ, Canberra, Aust); Moran, Grainne. *J Lumin* v 42 n 1 Jun-Jul 1988 p 21-27.

## Structure

**092431 ON THE TOPOLOGIES OF (M<sub>13</sub>)<sub>13</sub> SUPERCLUSTERS OF RUTHENIUM, RHODIUM AND GOLD.** A mechanism is proposed for the building of (M<sub>13</sub>)<sub>13</sub> superclusters and their transition to the normal structure, which has been observed experimentally by G. Schmid and N. Klein for M=Rh, Ru and Au. The cluster energies are determined for this purpose as a topologically approximated sum of pair potentials. A discussion is presented of two simple criteria for estimating the most stable cluster for a given number N of atoms: (i) the maximum A<sub>max</sub> of the total adjacency and (ii) the minimum W<sub>min</sub> of the Wiener index. (Edited author abstract). 10 Refs.

**Surface Properties** See ALKALI METAL COMPOUNDS—Adsorption.

## Surfaces

**092432 INTERACTION OF ALUMINUM WITH THE Ru(0001) SURFACE AND ITS INFLUENCE UPON CO CHEMISORPTION.** The interaction of vapor-deposited Al with Ru(0001) surface and its influence upon CO chemisorption has been studied in ultrahigh vacuum by use of Auger electron spectroscopy, thermal desorption mass spectroscopy, and low-energy electron diffraction (LEED). Below 670 K, the Al grows as an overlayer in (111) oriented islands. By 1170 K, Al penetrates the surface to form intermetallic compounds with the Ru, and a (√3 × √3)R30° LEED pattern dominates the surface structure. A new CO desorption state at 850-1050 K appears at submonolayer Al coverages, which is attributed to strong, direct, interaction between adsorbed CO and Al probably involving C-O bond cleavage. (Edited author abstract) 25 refs.

## Thin Films

**092433 PHOTODEPOSITION OF Ru ON InP AND GaInPAs. CATALYTIC AND ELECTRONIC PROPERTIES.** The authors restrict this investigation to Ru/InP and Ru/GaInPAs contacts. The large grain polycrystalline quaternary semiconductor has been chosen because of differences in surface chemistry. Experimental data show that the typical current enhancement upon metallization is found. The increase in catalytic activity is larger for InP. A somewhat lower overall photoactivity is noted for GaInPAs. 36 refs.

**RUTHENIUM COMPOUNDS** See Also CATHODES—Materials; COBALT COMPOUNDS—Processing; ORGANIC COMPOUNDS—Synthesis; POLYELECTROLYTES.

**092434 CONSTITUTION OF THE Mo-Ru SYSTEM.** The constitution of the Mo-Ru system was reinvestigated between 900 and 2000°C using metallography, X-ray diffraction, X-ray microanalysis, differential thermal analysis and dilatometry. The system is of the eutectic type with a eutectic temperature of 1955°C and a eutectic composition of about 42 at.% ruthenium. The maximum solubility of ruthenium in molybdenum is 32.4 at.%

ruthenium and of molybdenum in ruthenium is 51.5 at.% molybdenum at 1935°C. The only intermediate phase,  $\text{Mo}_2\text{Ru}_3$ , present between 36.7 and 39.4 at.% ruthenium is formed by a peritectoid reaction at 1915°C and is decomposed by a eutectoid reaction at 1143°C. The lattice parameters and the c/a ratio of the hexagonal ruthenium (molybdenum) solid solution increase with increasing molybdenum content. (Edited author abstract) 6 refs.

Kleykamp, H. (Kernforschungszentrum Karlsruhe, Karlsruhe, West Ger). *J Less Common Met* v 136 n 2 Jan 1988 p 271-275.

**092435 LUMINESCENT CHARGE-TRANSFER STATE OF RUTHENIUM-BIPYRAZINE COMPLEXES.** Using laser flash photolysis, excited-state absorption measurements on  $\text{Ru}(\text{bpy})_3^{2+}$  and  $[\text{Ru}(\text{bpy})_2(\text{bpz})]^{2+}$  were carried out in methanol (bpy is bipyridine; bpz is bipyrazine). Pulse radiolysis was used to produce spectra of one-electron-reduced forms of bpz which were compared with the excited-state spectra found in the laser flash photolysis experiments. A strong indication of the localization of the electron on one bpz ligand was observed, thus confirming a lower  $\pi^*$  level in bpz compared to the case of bpy. Decay rate constants and  $\text{O}_2$  quenching rate constants are also reported in water, methanol, and acetonitrile. This work is pertinent to solar energy conversion. (Edited author abstract) 52 refs.

**092436 EFFECT OF  $\text{RuO}_2$  ON THE BEHAVIOR OF SILVER AT THICK-FILM TERMINATIONS.** In an attempt to understand the silver-glass interactions at the electrode/resistor terminations in hybrid integrated circuits, the behavior of silver in binary  $75\text{PbO}-25\text{SiO}_2$  glass containing up to 20 wt.%  $\text{RuO}_2$  particles was studied between 650 and 850°C. It is shown that the dissolution of silver into glass increases with increasing amount of  $\text{RuO}_2$  particles. A different temperature dependence of dissolution was observed for  $\text{RuO}_2$ -free and  $\text{RuO}_2$ -doped glasses. Silver-ion- $\text{RuO}_2$  interactions have been proposed as a possible mechanism responsible for the increased dissolution of silver in glass. 6 refs.

**092438 FORMATION RATE AND GAS-LIQUID EQUILIBRIUM OF  $\text{RuO}_4$ .** The formation rate of ruthenium tetroxide ( $\text{RuO}_4$ ) from nitrosyl ruthenium trinitrate ( $\text{RuNO}(\text{NO}_3)_3$ ) was measured at temperatures of 70-115°C in 3-9 mol. $\text{dm}^{-3}$  nitric acid solutions. The gas-liquid equilibrium ratio was measured at temperatures at 40-80°C in 0.1-9 mol. $\text{dm}^{-3}$  nitric acid solutions. The gas-liquid equilibrium ratio of  $\text{RuO}_4$  ranged about 60-260 under the experimental conditions. The reaction rate increased greatly with acid concentrations above 6 mol. $\text{dm}^{-3}$ . The activation energy of the reaction was about

130 kJ. $\text{mol}^{-1}$  in 9 mol. $\text{dm}^{-3}$  nitric acid solution. It was concluded that the rate of  $\text{RuO}_4$  formation dominated the distill-out phenomena of Ru in an evaporator as used in nuclear fuel reprocessing plants. (Author abstract) 16 Refs.

## Electric Conductivity

**092439 ELECTRICAL PROPERTIES OF  $\text{A}_2[\text{Ru}_{2-x}\text{A}_x]\text{O}_{7-y}$  (A = Pb OR Bi) PYROCHLORES AS A FUNCTION OF COMPOSITION AND TEMPERATURE.** The variable stoichiometry pyrochlore compounds exhibit high electrical conductivity with room temperature values ranging from 10 to 1000 ( $\text{ohm}\cdot\text{cm}$ ) $^{-1}$ , dependent upon composition. For the lead-containing series, resistivity vs temperature data show that there is a smooth variation from a positive to a negative temperature coefficient of resistivity (TCR) as a function of increasing lead content. Substitution of approximately 20% of the ruthenium by lead results in a material with essentially temperature-independent resistivity. (Edited author abstract) 21 refs.

Beyerlein, R.A. (Exxon Research & Engineering Co, Annandale, NJ, USA); Horowitz, H.S.; Longo, J.M. *J Solid State Chem* v 72 n 1 Jan 1988 p 2-13.

## Electric Properties

**092440 ELECTROPHYSICAL PROPERTIES OF COMPOSITES BASED ON SOME RUTHENIUM COMPOUNDS.** The authors investigated resistivity at normal temperature and the temperature dependence of resistivity of  $\text{RuO}_2$  and  $\text{Bi}_2\text{Ru}_2\text{O}_7$  containing admixtures able to change the electrical properties (e.g., Cu, Ti, Mn, Fe with mass content not exceeding 10-2-10-3%). An analysis of the experimental data permits the conclusion that thick film resistive elements with resistivity of less than 5  $\Omega/\text{sq}$ . formed on ceramic VK 94-1 cannot be obtained from powdered  $\text{Bi}_2\text{Ru}_2\text{O}_7$  with specific surface of 10,000-12,000  $\text{cm}^2/\text{g}$ . Resistive elements with a resistance on the order of single ohms per square can be made on the basis of powdered  $\text{RuO}_2$ , but the problem of compensating the high positive temperature coefficient of electrical resistance arises. 9 refs.

## Electrochemistry

**092441 ELECTRICAL DOUBLE LAYER ON OXIDES: SPECIFIC ADSORPTION OF CHLORIDE AND METHYLVIOLGEN ON RUTHENIUM DIOXIDE.** The main purpose of this study is to gain insight into the electrochemical properties of the  $\text{RuO}_2$ -electrolyte interface and the interaction between  $\text{RuO}_2$  and  $\text{MV}^{2+}$  ions. It is demonstrated how quantitative data on specific adsorption can be obtained from  $\sigma_0$  and  $\zeta$ -potential measurements without introducing an inner-layer model, like the ones based on surface complexation or site binding. Our analysis is based on purely thermodynamic arguments combined with diffuse double-layer theory, and therefore has a general validity. In addition, we hope to contribute to the discussion about the common features of the double layer on oxide. 33 refs.

Kleijn, J.M. (Agricultural Univ, Wageningen, Neth); Lyklema, J. *J Colloid Interface Sci* v 120 n 2 Dec 1987 p 511-522.

## Forming

**092442 COMPLEXES OF  $\text{Ru(III)}$  WITH AMINOPOLYCARBOXYLIC ACIDS AND THEIR INTERACTION WITH MOLECULAR OXYGEN TO FORM  $\text{Ru(IV)}-\mu\text{-PEROXO}$  COMPLEXES.** The interaction of  $\text{Ru(III)}$  with IMDA, HEDTA, EDTA, PDTA,

CDTA and DTPA was studied by potentiometric and spectrophotometric methods at 25°C and 0.10 M ionic strength. Experiments were carried out under nitrogen and oxygen atmospheres. Evidence for the formation of dioxygen complexes in these systems is presented. Stability constants for the different species existing in each of the systems were calculated using a computer program. (Edited author abstract) 18 refs.

## Ion Implantation

**092443 DSA  $\text{RuO}_2/\text{TiO}_2$  ELECTRODE MODELED BY ION IMPLANTATION: AN IN SITU CHARACTERIZATION BY PHOTOACOUSTIC AND PHOTOCURRENT SPECTROSCOPY.** Ion implantation of ruthenium into titanium was used to produce near-surface alloys of controllable surface composition. The thin oxide layer that was formed in situ at the surface of the implanted alloy was taken as a model for  $\text{Ru}_x\text{Ti}_{1-x}\text{O}_2$  (DSA) electrodes. The time dependence of the surface ruthenium/titanium ratio in the mixed oxide was correlated to the original implant profile, measured by Rutherford backscattering, with the assumption of no preferential dissolution. The experimental results are interpreted in terms of a transition from a semiconducting layer to a metallic-like layer when the ruthenium/titanium ratio reaches a value of about 0.10. (Edited author abstract) 56 refs.

Vallet, C.E. (Oak Ridge Natl Lab, Oak Ridge, TN, USA); Borns, S.E.; Hendrickson, J.S.; White, C.W. *J Electrochem Soc* v 135 n 2 Feb 1988 p 387-395.

## Magnetic Properties

**092444 PHYSICAL PROPERTIES OF METAL CLUSTER COMPOUNDS V: MAGNETIC MEASUREMENTS ON LOW-NUCLEARITY (RUTHENIUM CARBONYL CLUSTERS).** We present magnetic susceptibility and magnetization measurements on a series of low-nuclearity ( $n=6$ ) ruthenium carbonyl clusters. It is shown that even these very small metal cluster have a fraction of unpaired spin density leading to a low-temperature divergent susceptibility and a magnetization that is far from saturated in fields up to 5 tesla. The effect of CO adsorption on the magnetic properties of a bare cluster is discussed. (Author abstract) 18 refs.

Phase Equilibria See RESISTORS—Thick Films.

## Reduction

**092446 COMPARATIVE STUDY OF ELECTROCHEMICAL REDUCTION OF RUTHENIUM COMPLEXES.** It was found that a complex with a binuclear structure which differs from the specially synthesized

complex  $K_3[Ru_2N(H_2O)_2Cl_8]$  with respect to the structure of the internal sphere is formed in an electrolyte. Hydrolysis and activation of the starting form of the complex, accelerated due to the necessity of conducting electrolysis at 70°C, is the cause of the instability of the electrolyte prepared from the binuclear complex  $K_3[Ru_2N(H_2O)_2Cl_8]$ . Electrolyte (I), in which equilibrium is rapidly established and the state of the ruthenium ions does not subsequently change, is preferred for prolonged electrolysis with stable characteristics of the cathode process. 13 refs.

## Spectroscopic Analysis

**092447 ENERGY TRANSFER AND HIGHLY RESOLVED EMISSION OF  $[Ru_{1-x}Os_x(bpy)_3](PF_6)_2$ .** The emission properties of the title compound are investigated at  $T = 2$  K and high magnetic fields. The radiationless energy transfer from the [Ru]-host to the [Os]-guest is governed by a fast process and a slow one, which indicates a relatively ineffective transfer in the host material. Moreover, the guest emission is found to be highly resolved and is assigned to result from a superposition of vibronic components emitted from three different sites. (Author abstract) 8 refs.

## Synthesis

**092448 SYNTHESIS, OXYGENATION AND CATALYTIC PROPERTIES OF RUTHENIUM(III) SALOPH COMPLEXES.** Synthesis and dioxygen affinities of ruthenium(III)-Schiff base complexes with various appended axial base ligands are reported. A mechanism is proposed for the conversion of cyclohexene to the epoxide, and a subsequent rate law derived with the help of which were determined the values of the rate and equilibrium constants. (Edited author abstract) 19 refs.

Taqvi Khan, M.M. (Central Salt & Marine Chemicals Research Inst, Bhavnagar, India); Mirza, Shaikat A.; Prakash Rao, A.; Sreelatha, C. *J Mol Catal* v 44 n 1 Feb 15 1988, Int Workshop on Homogen Catal: Act of Mol Oxygen and Catal Oxid by Dioxygen Compd, Bhavnagar, India, Oct 3-6 1986 p 107-115.

**Thin Films** See Also ANODES—Materials.

**092449 INFRARED AND X-RAY PHOTOELECTRON SPECTRA OF RUTHENIUM OXIDE FILMS AND RUTHENIUM HYDROXIDE.** The IR and x-ray photoelectron spectra of ruthenium hydroxide and of ruthenium oxide films produced by ruthenium chloride hydroxide decomposition at 300, 400, 500, and 600°C were examined in order to obtain information concerning the effect of hydration on the structure and electronic properties of the surface of ruthenium oxide (RO) electrodes. It was shown that Ru hydroxide and RO films contain, both water molecules and hydroxyl groups; the latter are retained up to higher temperatures (600°C) in the RO films than in Ru hydroxide. It was found that water makes the materials studied amorphous, and it also was found that hydration influences their electronic structure (valence band and the electronic core levels of Ru and O). (Author abstract) 33 refs.

## RUTHENIUM IRON BORON ALLOYS

### Amorphous

**092450 MAGNETISM IN AMORPHOUS  $Ru_xFe_{80-x}B_{20}$  ALLOYS: MAGNETIZATION AND MOSSBAUER STUDY.** Amorphous alloys of  $Ru_xFe_{80-x}B_{20}$ ,  $0 \leq x \leq 22$  have been investigated using low field ac susceptibility, dc magnetization and  $^{57}Fe$  Mossbauer spectroscopy. The magnetic phase diagram of  $Ru_xFe_{80-x}B_{20}$  is confirmed. Mossbauer measurements reveal a low temperature transition in  $Ru_{18}Fe_{62}B_{20}$  magnetization measurements indicate a noncollinear magnetic structure. The effect of substitution of Ru on distribution in exchange is discussed. (Author abstract) 13 refs.

Paulose, P.L. (Tata Inst of Fundamental Research, Bombay, India); Nagarajan, V.; Nagarajan, R.; Vijayaraghavan, R. *Solid State Commun* v 61 n 3 Jan 1987 p 151-155.

### Electric Conductivity

**092451 ELECTRICAL RESISTIVITY OF AMORPHOUS  $Ru_xFe_{80-x}B_{20}$  ALLOYS.** Amorphous  $Ru_xFe_{80-x}B_{20}$ ,  $0 < x < 22$  shows interesting changes in magnetic behavior with Ru concentration and temperature. In the course of our study of these alloys using a variety of techniques we have undertaken electrical resistivity measurements which probe the zero field ( $H=0$ ) state. For  $Ru_{18}Fe_{62}B_{20}$ , the electrical resistivity,  $\rho$ , as a function of temperature has a minimum around 106 K. In magnetic fields up to 1.8 Tesla the change in the  $\rho$  of  $Ru_{20}Fe_{60}B_{20}$  is small and within experimental errors. (Edited author abstract) 1 refs.

Paulose, P.L. (Tata Inst of Fundamental Research, Bombay, India); Nagarajan, V.; Vijayaraghavan, R. *Key Eng Mater* v 13 pt 2 1987, Int Conf on Met and Semicond Glasses (MSG-86), Hyderabad, India, Dec 16-20 1986 p 543.

## RUTHENIUM VANADIUM ALLOYS

### Phase Diagrams

**092452 RUTHENIUM-VANADIUM SYSTEM.** There are disparities in the reports of the compositions associated with Ru-rich solvus and the V-rich solvus. There is uncertainty as to the phase relationship between CsCl structure and the bcc V-rich terminal solution and there is a question whether or not a tetragonal phase that has been observed at lower temperatures in the central portion of the system is an equilibrium feature of the system. The discussion indicates the source of these uncertainties and reviews the currently available data. 15 refs.

Smith, J.F. (Iowa State Univ, Ames, IA, USA). *J Alloy Phase Diagrams* v 3 n 3 Sep 1987 p 133-138.

## S

## SAFETY VALVES See Also VALVES AND VALVE GEAR.

**092453 CALCULATING DISCHARGE OF GAS OR STEAM THROUGH SAFETY-VALVES.** The author presents a formula for calculating the flow-rate of gas or steam through a safety-valve. Solving the formula by conventional methods is somewhat time-consuming, so he has formulated a nomogram which allows the problem to be considerably simplified and to be solved with the aid of a ruler. SI (metric) units are used in the calculations, but the system is equally valid for English units, for which a corresponding formula and nomograph are also included.

Zanker, Adam. *World Pumps* Oct 1987 p 327-328.

**092454 VENT HEIGHTS FOR EMERGENCY RELEASE OF HEAVY GASES.** The safe disposal of releases to atmosphere via safety relief valves and Emer-

gency Relief Systems (ERS) requires adequate vent heights to produce tolerable concentrations of contaminants. Such releases occur generally upon pressure relief; they may be from liquified or, simply, gaseous systems. This paper describes a method developed to estimate vent heights for emergency releases of heavy gases to prevent flammability at exposed locations. 34 refs.

## Design

**092455 EFFECT OF THE RATE OF SEAL MOVEMENT IN THE POWER CHARACTERISTICS OF THE SAFETY VALVE.** To develop a reliable method of designing the safety valve, a study of the effect of the rate of seal movement on its power characteristics was made. Experiments were carried out in a safety valve model of  $D_u = 50$  mm. The model consists of a body with inlet and outlet nipples, and a seat on which the seal is pressed down by spring. The seal is fixed on a mobile stem. A special system was devised to record the locational coordinates of the seal relative to the seat and the rate of its displacement during the functioning of the valve. Using the derived dependence  $h(t)$ ,  $d^2h/dt^2$  was calculated by the numerical method. The calculations were made in a uniform grid in the high-accuracy nodes using the simplest (single member) equations and improved by the Runge-Romberg method. The results of  $f(h)$  calculations obtained by the method described above are given. It is shown that no significant differences of  $f(h)$  were noticed within the range of experimental errors ( $\pm 10\%$ ) at seal displacement rates  $h \leq 1$  m/sec. 5 refs.

**092456 RESISTANCE TO GAS/VAPOR-LIQUID FLOW IN SAFETY VALVES.** As a result of systematic statistical investigations of the reliability and general validity of expressions for calculation of the resistance to the flow of mixtures of air and water through full-stroke safety valves, the semiempirical check-valve equations of D. Chisholm with a coefficient of  $B=1.5$ , and P.E. Tremblay, stand out as the most accurate. They are also to be preferred for design calculations for other two-phase flows, since reliable knowledge does not exist for these. (Edited author abstract). 30 Refs.

## Noise Abatement

**092457 REVIEW OF THE DEVELOPMENT OF SAFETY AND RELIEF VALVE SILENCERS FOR STEAM DISCHARGE.** The paper outlines the progress made by the Central Electricity Generating Board (CEGB) in the development of silencers for the control of boiler safety valve and relief valve noise. System noise sources and the formulation of environmental noise criteria are discussed; the silencer design philosophy adopted by the CEGB is described and the progressive improvements are charted to demonstrate the advances made over earlier practices. The results of this work are design concepts which provide silencers which are suitable for application to any of the CEGB's steam valve vent systems and are capable of meeting stringent neighborhood noise criteria. (Author abstract) 7 refs.

## Pressure Control

**092458 DETERMINING THE CRITICAL PRESSURE RATIO IN THE FLOW SECTION OF A SAFETY VALVE.** When new types of safety fittings are developed and improvements made to existing ones, the main problems which arise are the optimization of the throughput capacity of the safety device and the development of effective methods of controlling such operating parameters as operating cycle pressure (pressure of com-

plete opening and closing), length of operating cycle, speed with which shut-off device moves into position. An analysis carried out showed that the parameters are determined by two integral characteristics - flowrate and force characteristics, which are taken here to mean the dependence of the flowrate of the working medium and the force on the slide valve from the flow side on the lift of the slide valve. 3 refs.

Borзов, B.A.; Kozlov, V.M. *Sov Energy Technol* n 7 1987 p 39-42.

## Reliability

**092459 QUALITY AND RELIABILITY OF SAFETY RELIEF VALVES.** The leading particulars of safety relief valve testing facilities, judged by the ISPESL Italian Control Authorities as being suitable and reliable, were singled out. These facilities enabled a whole cycle of experimental tests to be conducted in free blowdown and variable back pressure conditions, which led to the evaluation of the leading performance characteristics of a new series of safety relief valves in accordance with real working conditions. The protective function of these devices justifies the interest in any possible further improvement of their performance, quality and reliability.

**092460 JAPANESE ADVANCES IN TRANSPORT TECHNOLOGY.** Modern sail-assisted ships are designed to make use of natural wind power in order to improve fuel consumption. More than seven years ago, September 1980, the world's first sail-assisted commercial ship, the 699 G/T tanker Shin-Aitoku Maru, was completed. This fuel-efficient vessel was notable in that sail control was totally automated, requiring no extra crew. This article reviews the sail-assisted concept, and select design features of vessels that employ them.

## Aerodynamics

**092461 SIMPLE MULTILAYER PANEL METHOD FOR PARTIALLY SEPARATED FLOWS AROUND TWO-DIMENSIONAL MASTS AND SAILS.** A new multilayer panel method has been developed using superimposed combinations of vortex doublet and source/sink elements to predict the static pressure distributions found over two-dimensional mast/sail geometries. The method takes into account all the partially separated regions present, and all the computations are performed without any need for iteration. The only inputs required are: mast/sail geometry, aerodynamic incidence angle, freestream Reynolds number, and empirically determined separation and reattachment locations. All of the base pressures involved are obtained as part of the solution. Comparison between experimental and theoretical results showed excellent agreement. (Author abstract). 1 Ref.

## Design

**092462 TECHNOLOGY AND DESIGN FOR STARS & STRIPES.** The February 4, 1987 victory of STARS & STRIPES in the America's Cup races off Perth, Western Australia, was a culmination of a three-year project of broad scope and great intensity. The design/technology team approach used to develop the 12-meter yacht STARS & STRIPES is presented. The effort

includes three separate yacht-design firms, advanced computational tools, forty 1/3 scale model tests, and a very sophisticated full-scale yacht evaluation procedure. The total performance evaluation system, which integrates the myriad details of yacht designs and race tactics within the flow-code results into a single figure of merit, the relative speed of 12-meter yachts around the race course, is discussed. (Edited author abstract) 5 refs.

## Masts

**092465 WELDED MASTS MEAN SMOOTH SAILING AHEAD.** The article briefly outlines a GTA welding process for aluminum masts for sailing boats. The setup was designed to handle a variety of unique situations. The mast is clamped together for welding, but since the V-groove is cut with a circular saw, there can be variations in fitup, requiring torch adjustments. To compensate for distortion, the mast is pre-bent in the opposite direction of the weld.

## SALT MINES AND MINING

### England

**092468 TUNNELLING IN SALT: A MAJOR DEVELOPMENT PROJECT AT THE WINSFORD SALT MINE.** Winsford salt mine in Cheshire currently supplies some 80% of Britain's rock salt requirements for de-icing roads. This year the mine operators, ICI Mond Division, plan to produce 2.25 Mt rock salt, up from 1.85 Mt in 1986, in response to a growing demand from local authorities throughout the country. To meet this target, the company contracted out a major development project to extend underground room and pillar workings to the north east of reserves.

**092469 ELECTROACTIVE LANGMUIR-BLODGETT FILMS OF N-OCTADECYLPYRIDINIUM-TCNQ CHARGE-TRANSFER SALT.** Langmuir-Blodgett films of the 1:1 charge-transfer salt N-octadecylpyridinium-TCNQ have been deposited onto glass substrates. The layers exhibit significant bulk lateral conductivity without doping. The value obtained at room temperature is  $(2.0 \pm 0.2) \times 10^{-2} \text{ S cm}^{-1}$ ; over the temperature range 100 - 300 K, the films show typical semiconductor behaviour with an activation energy of  $0.13 \pm 0.005 \text{ eV}$ . Infrared and u.v.-visible transmission spectra of the films are characteristic of an organic conductor. (Author abstract) 9 refs.

**092471 SALT HYDRATES USED FOR LATENT HEAT STORAGE: CORROSION OF METALS AND RELIABILITY OF THERMAL PERFORMANCE.** Data are presented on the corrosion resistance of metallic alloys to hydrated salts, which may be utilized as phase change materials (PCM) for heat storage. With the same experimental apparatus, tests on the thermal performance reliability of PCM after repeated thermal cycling were carried out. Commercially available latent heat storage components containing the following salt hydrates with melting points between 15°C and 32°C have been considered:  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ ,  $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\text{Na}_2\text{SO}_4 \cdot 1/2\text{NaCl} \cdot 10\text{H}_2\text{O}$ ,  $\text{NaOH} \cdot 3.5\text{H}_2\text{O}$ . The containment materials tested were stainless steel, carbon steel, Al alloys, and Cu. As many as 5650 thermal cycles involving repeated melting and freezing of the phase change materials were carried out. The most corrosion-resistant alloy to all the hydrated salts tested was stainless steel. Only the two commercial  $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$  tested showed good thermal stability after repeated thermal cycling. (Author abstract). 10 Refs.

**092472 INTERFACIAL BEHAVIOR OF TETRAALKYLAMMONIUM IONS AT THE Hg ELECTRODE IN GLYCOLS.** The adsorption behavior of tetramethyl-, tetraethyl-, and tetrabutylammonium cations on Hg from glycol solutions has been investigated by capacitance measurements both in the presence and absence of a supporting electrolyte. The surface activity is governed by both electrostatic and lyophobic factors. The former are important for small negative charges and low ionic strengths. Lyophobic factors become progressively predominant as the ionic size increases. A preliminary comparison has been made of tetraalkylammonium ions in ethylene glycol, 1,2- and 1,3-propylene glycol. (Author abstract) 28 refs.

**092473 MULTIPLE EQUILIBRIA MODEL OF THE ADSORPTION OF OLEATE AQUEOUS SPECIES AT THE GOETHITE-WATER INTERFACE.** The interaction between monomers and dimeric aqueous oleate species and ionizing groups at the goethite-water interface has been constructed to analyze experimental surface change titration and oleate adsorption isotherms. The binding constants that emerge and the pH-concentration distribution of surface oleate complexes support the concept of anion-neutral molecule coadsorption or acid soap dimer adsorption in the region where precipitation of oleic acid and/or ferric oleate is precluded. 19 refs.

Jung, R.F. (Univ of Melbourne, Parkville, Aust); James, R.O.; Healy, T.W. *J Colloid Interface Sci* v 122 n 2 Apr 1988 p 544-549.

**092474 EFFECT OF INORGANIC SALT ON ADSORPTION OF SODIUM ALKYL SULFATES AND FATTY ACID SODIUM SALTS FROM AQUEOUS SOLUTION ONTO ION EXCHANGE RESINS.** The adsorption isotherms of sodium salts of alkyl sulfonic acid and fatty acid with various carbon numbers onto ion exchange resins were measured in the absence and in the presence of sodium chloride in aqueous solutions. In the absence of the inorganic salt, the amount of adsorption remarkably increased with an increase in the length of alkyl groups in the adsorbates. Furthermore, the amount of adsorption apparently decreased with addition of sodium chloride into the solutions and almost reached a constant value at high concentrations of NaCl. This behavior strongly suggested that the electrostatic interac-

tion on the adsorption decreased with increasing salt concentration and that the effect of hydrophobic interaction seems to play an important role on adsorption. (Author abstract). 9 Refs.

Ihara, Yasuji (Yamaguchi Women's Univ, Yamaguchi, Jpn). *J Appl Polym Sci* v 36 n 4 Aug 5 1988 p 891-897.

**092475 ADSORPTION MODEL OF PYRIDINIUM SALTS ON QUARTZ.** On the basis of adsorption and flotation measurements using a new flotation apparatus an adsorption model of pyridinium salts on quartz is presented. Depending on the character of the counterions the maximum amount of surfactant adsorbed is a bilayer or a tetralayer. Measurements of the flotation rate at various electrolyte concentrations show sharp maxima at surfactant concentrations near critical micelle concentration (CMC)/2. If the flotation rate is a function of the surface hydrophobicity, then the first adsorption layer is completed at this surfactant concentration. The dependence of the flotation rate on phosphate concentration shows three sharp flotation maxima that do not correspond to those measured in the presence of sulfate ions. The shift of the first two maxima is explained as a chemical change of the quartz surface induced by the phosphate ions. The small third maximum may be caused by a further adsorption layer that is weakly bound to the surface. (Edited author abstract). 18 Refs.

## Analysis

**092476 GAS CONTENT DETERMINATIONS OF SALT SAMPLES USING ACOUSTIC RESPONSES.** The Bureau of Mines has developed a practical methodology for determining occluded gas contents of domal rock salt samples. The method, which is portable and field-worthy, provides results in 5 min or less and does not require a laboratory environment or specially trained personnel to obtain meaningful results. The results can be used to identify gas-enriched zones, and thus may aid mine operators in production planning or ventilation design. The test method is based on the relationship between gas content and the acoustic response of salt samples as they are dissolved in water. The relationship is defined by an equation, and the results are repeatable. The equation was derived by testing a series of rock salt samples collected from domal salt mines in Louisiana. (Author abstract) 14 refs.

## Chemical Vapor Deposition

**092477 LABORATORY STUDIES OF BINARY SALT CVD IN COMBUSTION GAS ENVIRONMENTS.** A flash-evaporation technique is used to obtain vapor deposition characteristics for the binary alkali sulfates  $\text{K}_2\text{SO}_4$  +  $\text{Na}_2\text{SO}_4$  at 1 atm above 1,100 K. This technique gives results of immediate engineering interest, such as dewpoint temperatures, condensate composition and rates of vapor deposition as well as useful data on the system's thermodynamic characteristics. It is concluded that alkali sulfate deposition and vaporization in combustion environments are inevitably influenced by chemical reactions such as hydroxide formation. It is also concluded that solution nonideality is important even for homologous alkali-salt mixtures. (Edited author abstract) 34 refs.

**092479 SEPARATION OF SULPHONIUM SALTS BY ION CHROMATOGRAPHY: FIVE- AND SIX-MEMBERED CYCLIC SULPHONIUM SALTS.** Several cyclic 5- and 6-membered sulphonium compounds were separated by ion pair chromatography on an opti-dbb ion pair column. The salts show specific retention behavior when using different mixtures of acetonitrile and aqueous sodium perchlorate solutions as eluents. The increase of retention times with extending chain length of the alkyl group R and with ring size is due to an increase of the solute molecular surface areas which were also calculated. The obtained retention parameters give additional information for structural determination. (Author abstract) 12 refs.

Aced, Gaby (Hann-Meiner-Inst Berlin GmGh, Berlin, West Ger); Anklam, Elke; Mockel, Hermann J. *J Liq Chromatogr* v 10 n 15 Nov 1987 p 3321-3327.

**092480 SOLUTE-SOLVENT INTERACTIONS IN LIQUID TETRABUTYLAMMONIUM SULFONATE SALTS STUDIED BY GAS CHROMATOGRAPHY.** The gas chromatographic properties of 11 tetrabutylammonium sulfonate salts containing proton donor/acceptor substituents incorporated into the sulfonate anion are described. Several of these salts are liquid at room temperature and can be used as stationary phases at temperatures up to 160-200°C. These salts retained polar solutes largely by gas-liquid partitioning although interfacial adsorption was significant for the n-alkanes, particularly for the anions containing hydroxyl and acetamide substituents. (Edited author abstract) 19 refs.

## Creep

**092481 EFFECT OF SIMULATED SAMPLING DISTURBANCE ON CREEP BEHAVIOUR OF ROCK SALT.** This article presents the results of an experimental study of creep behaviour of a rock salt under uniaxial compression as a function of prestrain, simulating sampling disturbance. The prestrain was produced by radial compressive loading of the specimens prior to creep testing. The tests were conducted on an artificial salt to avoid excessive scattering of the results. The results obtained from several series of single-stage creep tests show that, at short-term, the creep response of salt is strongly affected by the preloading history of samples. The nature of this effect depends upon the intensity of radial compressive preloading, and its magnitude is a function of the creep stress level. The effect, however, decreases with increasing plastic deformation, indicating that large creep strains may eventually lead to a complete loss of preloading memory. (Author abstract) 34 refs.

## Crystal Lattices

**092482 ON THE  $\text{Eu}^{2+}$  -  $\text{Mn}^{2+}$  ENERGY TRANSFER IN  $\text{BaMgF}_4$ .** Energy transfer from  $\text{Eu}^{2+}$  to  $\text{Mn}^{2+}$  ions is shown to occur in  $\text{BaMgF}_4$ : Eu, Mn crystals. The efficiency of this transfer is moderate. This is attributed to the fact that  $\text{Eu}^{2+}$  and  $\text{Mn}^{2+}$  ions are distributed randomly in the host lattice. Quantitative evaluation leads to the suggestion that the transfer is restricted to only seven neighbors at 4.0 Å and is thus exchange mediated. (Author abstract) 9 refs.

Srivastava, A.M. (Polytechnic Univ, Brooklyn, NY, USA); Sobieraj, M.T.; Ruan, S.K.; Banks, E. *Mater Chem Phys* v 19 n 3 Apr 1988 p 199-204.

## Crystallization

**092483 KINETICS OF MASS CRYSTALLIZATION OF SALTS FROM SOLUTIONS IN IDEAL MIXERS.** Experiments were conducted in an experimental crystallizer with a dual circulation circuit. In conducting the experiments, the consumption of the starting feed solution saturated with potassium chloride at the temperature of 50-55°C was  $0.3 \cdot 10^{-5} \text{ m}^3/\text{sec}$ , the efficiency of the installation with respect to the solid state was  $2.7 \cdot 10^{-2} \text{ kg}/(\text{m}^3 \cdot \text{sec})$ , and the temperature in the apparatus was 16-20°C. A comparison of the scattering of the experimental points with the width of the confidence interval confirms the fluctuational character of the dependence of the average size of the crystals on time. The method for calculating the supersaturation, which arises in ideal mixing apparatus as a function of the available supersaturation  $x_p$ , is the ratio of the characteristic times of creation to elimination of supersaturation  $\mu$  and the time of creation of supersaturation  $\tau_c$  to the average time of residence of the crystals in the apparatus  $t$  permits selecting the required geometric dimensions of the apparatus. 5 refs.

Zel'manov, G.Z. *J Appl Chem USSR* v 60 n 6 pt 1 Jun 1987 p 1222-1225.

**092484 METHOD OF CALCULATING SALT CRYSTALLIZATION FROM SOLUTION INVOLVING RECIRCULATION.** To obtain coarse-grained dust-free salts by mass crystallization from solution, it is desirable to recirculate a fraction of the finished crystals. In this connection, considerable interest attaches to a recirculation model for the stationary and transient states, as well as results on the effects of grain size and amount of the returned crystals on the nucleation kinetics and crystal growth. The authors have analyzed the transient response in recirculation crystallization of salts from solution. The experiments were performed with an experimental crystallization system including a horizontal crystallizer containing a frame stirrer of capacity 0.01 m<sup>3</sup>, tanks for the initial saturated solution and suspension, together with the necessary auxiliary equipment and measuring instruments. The flow rate for the potassium chloride feed solution was 48 liter/h, temperature 67-70°, density  $1.205 \cdot 1.207 \times 10^3 \text{ kg}/\text{m}^3$ , temperature of suspension in apparatus 53-55°, and density of mother liquor  $1.198 \cdot 1.200 \times 10^3 \text{ kg}/\text{m}^3$ . The results show that the time required to reach the stationary state was virtually the same under all conditions and was determined only by  $k$  (2.5, 5, or  $10 \text{ h}^{-1}$ ). 7 refs.

Zel'manov, G.Z. (All-Union Halurgy Research & Development Inst, USSR); Shchusser, M.B.; Seballo, V.A. *J Appl Chem USSR* v 59 n 6 1 Jun 1986 p 1154-1157.

**092485 KINETICS OF THE HYDROLYTIC DECOMPOSITION OF PERXENATE IONS IN ACIDIC SOLUTIONS.** The hydrolytic decomposition of perxenate ions in acidic solutions has been investigated by kinetic fluorimetry. It is shown that perxenate ions are effective quenchers of excited  $\text{Tb(III)}$  ions. The rate

constant for the quenching of excited  $\text{Tb(III)}$  ions and the bimolecular rate constant for the deactivation of  $\text{Tb(III)}$  by perxenate ions are determined from the Stern-Volmer equation. The deactivation process is attributed to the oxidation of the excited  $\text{Tb(III)}$  ions by perxenate ions. The rate constant for the hydrolytic decomposition of perxenate ions is determined. (Author abstract) 9 refs.

**092488 (BEDT-TTF) $_2\text{CuCl}_2$ , A NEW CONDUCTING CHARGE TRANSFER SALT.** (BEDT-TTF) $_2\text{CuCl}_2$ , synthesized by oxidation and by electrocrystallization, has been characterized by single crystal X-ray diffraction, four-probe electrical conductivity, EPR and magnetic susceptibility, and shown to be semiconducting with  $\sigma \approx 4 \times 10^{-2} \text{ S cm}^{-1}$  at 290 K and  $E_g = 0.3 \text{ eV}$ . Static magnetic susceptibility and EPR measurements suggest strongly that the material is magnetic, consisting of strongly localized spins ( $S = \frac{1}{2}$  per BEDT-TTF dimer) with one-dimensional antiferromagnetic exchange. (Edited author abstract) 16 refs.

**092489 ELECTRICAL CONDUCTIVITY OF MOL-TEN  $\text{B}_2\text{O}_3\text{-Na}_2\text{O}$  MIXTURES.** The conductivity of mixtures of boron oxide and sodium oxide was measured in concentration and temperature ranges extending respectively from 0 to 33 mole%  $\text{Na}_2\text{O}$  and from 1023 to 1273 K. Different conductimetric cells were used in order to fit the cell factor to the electrolyte concentration. Equivalent conductance isotherms were determined assuming that  $\text{B}_2\text{O}_3$  acts as a solvent; the equivalent conductance of the melts increases with the  $\text{Na}_2\text{O}$  content. The temperature dependence is correctly described by an Arrhenius equation at all compositions. The preexponen-

tial factor does not significantly change with the basicity of the melt; the concentration dependence of the equivalent conductance is thus entirely brought about by the changes of the activation energy. (Author abstract) 7 refs.

**092490 ELECTRICAL CONDUCTIVITY OF ACID CRYSTALLOHYDRATE  $\text{MgHPO}_4 \cdot 3\text{H}_2\text{O}$  AND ITS STRUCTURAL TRANSFORMATIONS.** Electrical and thermal characteristics of solid  $\text{MgHPO}_4 \cdot 3\text{H}_2\text{O}$  have been investigated in a temperature interval from 20-400°C, and correlated with data of X-ray diffraction analysis. It is noted that in the temperature interval from 20-140°C, despite the presence of considerable hydrogen concentrations, the sample shows very small electrical conductivity. This is a consequence of crystal structure, where the strongest hydrogen bond exists between acid proton and oxygen of  $\text{PO}_4^{3-}$  group. The strong hydrogen bond decreases the number of potential electric carriers and prevents rotation of the  $\text{PO}_4^{3-}$  acceptor group, which causes crystallohydrate to show poor conductivity. With the breakage of crystal structure, caused by dehydration, amorphous  $\text{MgHPO}_4$  salt is formed and conductivity abruptly increases. At about 550°C crystallization starts and the newly formed phase  $\text{Mg}_2\text{P}_2\text{O}_7$  again shows poorer conductivity. (Author abstract) 15 refs.

**092491 REACTION OF TETRAMETHYLTETRASELENAFULVALENE (TMTSF) WITH COPPER (II) HALIDES AND THE ELECTRICAL PROPERTIES OF THE PRODUCTS.** The semiconductive compounds  $[(\text{TMTSF})_{1/2}]_2$  (room-temperature powder conductivity  $\sigma_{\text{RT}} = 9 \times 10^{-2} \text{ S cm}^{-1}$  and activation energy  $E = 0.07 \text{ eV}$ ) and  $(\text{TMTSF})_2\text{Br}_2$  ( $\sigma_{\text{RT}} = 7 \times 10^{-4} \text{ S cm}^{-1}$  and  $E = 0.18 \text{ eV}$ ) were obtained by redox reactions between TMTSF and copper (II) halides. These compounds were characterized with the aid of infrared, electron spin resonance and X-ray photoelectron spectroscopies, and thermoelectric power and magnetic susceptibility measurements. In contrast with common TMTSF and TTF conductors,  $(\text{TMTSF})_2\text{CuBr}_2$  had a large negative thermoelectric power. This property can be explained on the basis of the excess electrons produced on TMTSF by the transfer of electrons from  $\text{Cu}^2+$  to TMTSF (Author abstract) 17 refs.

**092492 MICROWAVE CONDUCTIVITY IN THE PURE AND IODINE-DOPED ORGANIC CONDUCTOR  $\alpha$ -(BEDT-TTF) $_2\text{I}_3$ .** The microwave conductivity in dependence of temperature was measured on pure and iodine doped crystals of  $\alpha$ -(BEDT-TTF) $_2\text{I}_3$  along the stack direction [100] and perpendicular to it [010]. The exposure times to iodine were varied in many steps between 2 min and 360 min. The contactless microwave technique enables to keep the same crystal in each case throughout all measurements. The results show that the microwave conductivity vs. temperature is not influenced distinctly by iodine doping. Only at the onset of the plateau range immediately below the metal-insulator transition at 135 K a small enhancement of the conductivity is found for exposure times larger than 60 min. In no case a transition to a superconducting state is observed. Therefore recently reported superconductivity may be due to surface effects. (Author abstract) 7 refs.

## Electronic Properties

**092493 ELECTRONIC EXCITATIONS IN (BEDT-TTF)-SALTS.** The indicatrix orientation, the birefringence, and the transmission spectra were measured in small crystals of the organic conductors  $\alpha$ -(BEDT-TTF) $_2$ I $_3$  and  $\alpha$ -(BEDT-TTF) $_3$ (NO $_3$ ) $_2$  in the near infrared (NIR) and the visible (VIS) spectral range. The results are discussed with regard to the orientation of the BEDT-TTF molecule axes and the arrangement of the intermolecular contact directions. The principal polarizabilities are calculated by composing the polarizabilities along the BEDT-TTF molecule axes and along the several contact directions. At high energies ( $\geq 2$  eV) in the VIS the orientation of the polarizability tensor is governed by the orientation of the stack forming molecules due to the intramolecular excitations. In the NIR the intermolecular excitations become dominant. The transmission spectra are compared with calculations of the dipole interactions. 4 refs.

Helberg, H.W. (Univ Goettingen, Goettingen, West Ger). *Ber Bunsenges Phys Chem* v 91 n 9 Sep 1987, Discuss Meet: Phys and Chem, of Unconv Org Mater, Wiesbaden-Naurod, West Ger, Apr 29-May 1 1987 p 899-901.

**092494 NEW ASPECTS OF THE INFRARED STUDY OF ELECTRON-PHONON COUPLING.** The temperature dependence of the spectral properties of dimerized TCNQ salts is explained in terms of an isolated dimer model. The cases of one and two electrons per dimer are considered separately, because the electron-electron interaction should be treated in an explicit way in these solids. An important new observation is that the changes in electronic interactions depend both on frequency and temperature. Hence, the thermal changes in the spectral properties manifest themselves by the variations of molecular band intensities and by the shift of their positions. The analysis of the Re  $(1/\rho(\omega))$  function, which can be calculated from reflectivity data, is claimed to allow the temperature dependence of the electron-molecular vibration coupling parameters to be determined unambiguously. (Author abstract) 5 refs.

**092500 STRUCTURAL INVESTIGATION OF THE MOLTEN SYSTEM LiCl-CaCl $_2$  BY X-RAY DIFFRACTION METHODS.** The structures of the molten system (LiCl) $_x$ (CaCl $_2$ ) $_{1-x}$ , with  $x = 1, 2/3, 1/2$ , and 0, were investigated by X-ray diffraction analysis. The coordination number obtained for the nearest-neighbor pair LiCl,  $N_{Li/Cl}$ , in molten LiCl was interpreted by the volume expansion  $\Delta V_f/V_s = (26.2\%)$  on melting. In molten CaCl $_2$ , the obtained bond-lengths and coordination numbers obtained for the nearest neighbor ionic pairs were close to those found in the crystalline form, which are consistent with the abnormally small  $\Delta V_f/V_s = (0.9\%)$ . The values of  $N_{Li/Cl}$  and  $N_{Ca/Cl}$  in molten LiCaCl $_3$  and Li $_2$ CaCl $_4$  are similar to those found in molten LiCl and CaCl $_2$ , respectively. In addition, over the whole range of concentration in this molten system, the nearest-neighbor bond length  $l_{Li-Cl}$  showed a linear dependence on molar fraction. The behavior in this system can be considered to be a result of the strongly Coulombic attractions between Li $^+$  or Ca $^{2+}$  and Cl $^-$ , which implies the formation of certain ionic groups. Experimental results by X-ray

structural analysis have directly given evidence for ionic groups. (Edited author abstract) 34 refs.

**092502 DATABASE AND SUBLATTICE MODEL FOR MOLTEN SALTS.** A thermodynamic database for molten salt solutions is being developed through the systematic optimization of binary and ternary data. Over 200 systems have been evaluated. Parameters for the subsystems of the Li, Na, K / F, Cl, OH, CO $_3$ , SO $_4$  system are tabulated. For calculating activities in multicomponent solutions, a sublattice model is used. Equations for integral and partial properties are given in full. For each sublattice it is shown how a consistent 'Kohler-Toop' (or 'Muggianu-Toop') formalism can be devised for multicomponent systems. The practical significance and importance of the various terms in the sublattice model as applied to molten salts are discussed. An example of automatic accessing of the multicomponent salt database for equilibrium calculations with a particular system is presented. (Edited author abstract) 32 refs.

Pelton, Arthur D. (Ecole Polytechnique de Montreal, Montreal, Que, Can). *Calphad* v 12 n 2 Apr-Jun 1988 p 127-142.

**092503 SHAPE OF RAMAN SPECTRA OF MOLTEN KNO $_3$ -NaNO $_2$  SOLUTION.** The Raman spectra of molten KNO $_3$ -NaNO $_2$  at 473-623 K have been measured. The regularity of the shape was investigated. The symmetrical stretching frequency peak  $\nu_1$  of NO $_3^-$  or NO $_2^-$  becomes broader as the temperature increases or the concentration decreases. The results are discussed based on the view point of a theoretical model obtained in previous work. (Edited author abstract) 4 refs. In Chinese.

## Geochemistry

**092504 EXTRACTION OF ELECTROLYTES-FORM UNCONSOLIDATED SEDIMENTS USING SATURATED PASTE AND FREEZING.** The determinations of the total amount and composition of soluble electrolytes (usually defined as position of soluble electrolytes (usually defined as 'soluble salts') is the first basic step in engineering geochemical investigations. In the author's initial studies in California and Nevada, the standard, generally accepted pedological method for the preparation of saturated soil pastes and their extraction was originally used for determinations of the amount and composition of salts. A new method requiring less personnel attention and more suitable for geologic purposes was developed, however, during the last decade and successfully used in this study. This note briefly describes and critically evaluates both methods. 6 refs.

## Hydrogenation

**092505 HYDROGENATION AND STRUCTURAL CHANGES IN POTASSIUM DITHIOFERRATE UNDER HEAT TREATMENT.** Polycrystalline potassium dithioferrate ( $KFeS_2$ ) was studied using X-ray diffraction to detect structural changes occurring in the compound when submitted to heat treatment at a temperature of 500°C under vacuum and in a hydrogen atmosphere. The changes observed in samples treated under vacuum and in a hydrogen atmosphere were similar, suggesting the presence of a new unstable phase coexisting with that of the untreated sample, and that the structural transformation observed is supposed to be primarily induced by the high-temperature treatment. (Edited author abstract) 29 refs.

Torriani, I.L. (Univ Estadual de Campinas, Campinas, Brazil); Arguello, Z.P.; Filho, A.R. Freira; Suassuna, J.P.; Taft, C.A. *J Mater Sci* v 23 n 3 Mar 1988 p 1068-1070.

## Ionic Conduction

**092506 ELECTRICAL CONDUCTIVITY AND PHASE DIAGRAM OF THE  $Na_2SO_4$ - $CaSO_4$  SYSTEM.** Very high vacancy concentrations may be obtained in solid solutions of the high temperature phase of  $Na_2SO_4$ . In this paper the  $Na_2SO_4$ - $CaSO_4$  system has been studied using differential scanning calorimetry (DSC) impedance spectroscopy and X-ray powder diffraction. The phase diagram, especially the stability range of the solid solution of the high temperature  $Na_2SO_4$  phase, has been redetermined. The electrical conductivity of this solid solution increases rapidly with increasing  $CaSO_4$  content and reaches a maximum for about 5 mol%  $CaSO_4$ ; the conductivity at e.g. 300°C,  $3.5 \times 10^{-3} (\Omega \text{ cm})^{-1}$ , is almost three orders of magnitude higher than that of pure  $Na_2SO_4$ . (Author abstract) 33 refs.

## Magnetic Properties

**092507 RADICAL ANION SALTS OF  $N,N'$ -DICYANOQUINONEDIMINE (DCNQ): CONDUCTIVITY AND MAGNETIC PROPERTIES.** DC-conductivity ( $\sigma$ ), static susceptibility ( $\chi$ ), ESR-intensity, resonance position and linewidth of ( $R_1$ ,  $R_2$ - $N,N'$ -DCNQI) $_2$ Me ( $R_1 = CH_3$ ;  $R_2 = CH_3$ , Cl, Br; Me = Ag, Cu) between 300 K and 1.2 K are reported. All copper salts have a high  $\chi$  of about  $5.6 \cdot 10^{-4}$  emu/mole in the conducting temperature range. This can be explained by strong electron-electron repulsion. In two salts, a CDW driven phase transition is seen and antiferromagnetic resonance (AFMR) is found below 10 K. The lack of any ESR signal in the conducting state is due to strong spin-orbit coupling (SOC) given by the nitrogen(p)-Cu(d) admixture which implies some electronic transport across the stacks. The silver salts do not exhibit these features. They behave as quasi-one dimensional conductors with reduced SOC effects. The conductivity is limited solely to the anion stack. Consequently, 1D-localization effects dominate the temperature dependence of the conductivity. (Author abstract) 16 refs.

**092508 ANGULAR DEPENDENCE OF FIELD INDUCED TRANSITIONS AND RAPID OSCILLATIONS IN  $(TMTSF)_2ClO_4$ .** We report studies of the angular dependence of the transition fields for the magnetic field induced spin density wave (FISDW) states and of the frequency of the rapid magnetic oscillations in the Bechgaard salt  $(TMTSF)_2ClO_4$ . As H is rotated away from  $c^*$ , the transition field positions and the oscillation frequency increase, exhibiting the conventional inverse

cosine behavior expected for an anisotropic electronic system. The results verify that both effects are orbital and two dimensional in nature. We find no evidence for a nonmonotonic behavior of the threshold field with angle that has been predicted by a recent theory. (Author abstract) 22 refs.

**092511 SPECIFIC ELECTRIC CONDUCTIVITY OF MOLTEN  $CaF_2$ - $CaCl_2$ ,  $SrF_2$ - $SrCl_2$  AND  $BaF_2$ - $BaCl_2$  MIXTURES.** The specific electric conductivity of  $CaF_2$ - $CaCl_2$ ,  $SrF_2$ - $SrCl_2$  and  $BaF_2$ - $BaCl_2$  binary salt melts was studied in the complete concentration range up to temperatures of the order of 1500°C. It was established that conductivity, measured for individual chlorides and certain fluoride-chloride mixtures in a broad temperature range, differs significantly from Arrhenius behavior. Specific electric conductivity isotherms at 1500°C in all three systems are characterized by significant negative deviations from additivity. Experimental results of the temperature dependence of specific electric conductivity were analyzed by the method of least squares and were tabulated. (Author abstract) 11 refs.

p 491-507.

## Optical Properties

**092513 PHOTOCROMIC BEHAVIOR OF VI-LOGENS AND POLYVILOGENS IN POLYMER MATRICES.** The photochromic behavior of viologens ( $V^{2+}$ ) and polyviologens ( $PV^{2+}$ ) was investigated using poly(N-vinyl pyrrolidone) (PVP) and poly(vinyl alcohol) (PVA) as matrices. In the PVP matrix the coloration rate of butylviologen bromide increases with decreasing humidity, but no influence of humidity on coloration rate was observed in the PVA matrix. The coloration rate in the PVA matrix follows a second-order plot while in the PVP matrix it does not. These results imply that, for the coloration process of viologens in polymer matrices, the effect of the matrix polymer as an electron donor must be considered. (Edited author abstract) 9 refs.

Chen, Y.L. (Zhongshan Univ, Guangzhou, China); Guan, Y.J.; Mai, Y.L.; Li, W.; Liang, Zh.X. *J Macromol Sci Chem* v A25 n 2 1988 p 201-210.

**092514 OPTICAL STUDY ON BIS-PROPYLENEDITHIOTETRATHIAFULVALENIUM (BPDT-TTF) SALTS.** Polarized reflectance spectra of semiconductive  $(BPDT-TTF)_3(PF_6)_2$  and  $(BPDT-TTF)_3I_3$  were measured at room temperature over the spectral region from 720  $\text{cm}^{-1}$  to 25,000  $\text{cm}^{-1}$ . Both of these salts exhibited one-dimensional behavior in contrast to the BEDT-TTF (bis-(ethylenedithio)tetrathiafulvalenium) salts. The transfer integrals and the on-site Coulomb energy of these materials were estimated by analyzing the optical spectra, and the on-site Coulomb energy of  $(BPDT-TTF)_3(PF_6)_2$  was found to be significantly larger than that of TCNQ salts. (Author abstract) 23 refs.

**092515 OPTICAL ABSORPTION OF SELENITE SINGLE CRYSTALS SUBJECTED TO HIGH ELECTRIC FIELDS AND IRRADIATED WITH X-RAYS OR  $\gamma$ -RAYS.** Owing to the utility of some divalent metal sulphates (e.g. barytes and selenites) doped with rare earths for dosimetry work, some interest has been developed recently, in the investigation of their physical properties. It is the aim of this letter to present measurements on the optical absorption of selenite single crystals together with its thermal bleaching properties in the region of 200 to 700 nm before and after X-ray or  $\gamma$ -ray irradiation under high a.c. or d.c. electric fields. From the present investigation of the optical absorption of selenite single crystals the two peaks lying at 236 and 400 nm, which disappear around bleaching temperatures of 140 and 330°C, respectively, may be ascribed to the weaker and stronger bonds of the water of crystallization present in selenite single crystals. 8 Refs.

**092517 STRUCTURE AND PROPERTIES OF A NEW CONDUCTING ORGANIC CHARGE-TRANSFER SALT  $\beta$ -(BEDT-TTF) $_2$ AuBr $_2$ .** A new conducting organic charge-transfer salt,  $\beta$ -(BED-TTF) $_2$ AuBr $_2$  has been synthesized and its crystal structure determined. Single crystal four-probe conductivity has been measured at ambient and applied pressures from 300-1.4K and EPR spectroscopy from 300-4.2K.  $\beta$ -(BED-TTF) $_2$ AuBr $_2$  crystallizes in PI (Z=1) with  $a = 9.020(1)$ ,  $b = 5.707(9)$ ,  $c = 16.320(1)$  Å;  $\alpha = 97.60(1)$ ,  $\beta = 92.12(1)$ ,  $\gamma = 102.89(1)$ ;  $V = 811.8(2)$  Å $^3$ . While the electronic properties are two-dimensional, the molecular packing of the BEDT-TTF molecules is slightly different from that found in other  $\beta$ -phase BEDT-TTF salts with triatomic counterions.  $\beta$ -(BEDT-TTF) $_2$ AuBr $_2$  is metallic to 1.4K at pressures up to 5.6 kbar although at all pressures studied there is appreciable hysteresis in the cooling and warming cycles of the conductivity between 6 and 14K. Abrupt transitions in the temperature dependence of both the peak-to-peak EPR linewidth and integrated signal intensity occur near 20K. The possibility of a low temperature structural modification is discussed. (Author abstract) 28 refs.

#### Research

**092518 PROTON POSITIONS AND THE HYDROGEN BONDING SCHEME IN SOME DIAMAGNETIC TUTTON'S SALTS—SINGLE CRYSTAL PMR STUDY.** Single crystal proton magnetic resonance (PMR) studies of three diamagnetic Tutton's salts, K $_2$ M(SO $_4$ ) $_2$ ·6H $_2$ O, M=Cd, Mg and Zn, are reported. The proton positions in these salts are determined using El Saffar's empirical procedure. The hydrogens participate in bonding with the oxygens of the sulfate groups. The H-bonding is estimated to be very strong since the H...O $_s$  length is smaller than 2.6 Å. the O $_w$ ...H...O $_s$  hydrogen bond is non-linear (approximately 173°), and plays a dominant role in determining the crystal packing. (Author abstract) 7 refs.

**092519 PHASE EQUILIBRIA IN THE SYSTEM Na $_2$ NH $_4$  | SO $_4$ , H $_2$ PO $_4$ ·H $_2$ O AT 25°C.** The purpose of this work was to construct a diagram for solubility and for activity of water in saturated solutions of the quaternary reciprocal system Na $_2$ NH $_4$  | H $_2$ PO $_4$ , SO $_4$ ·H $_2$ O at 25° from data on phase equilibria in the ternary subsystems, and to study experimentally the solubility diagram in order to verify the calculated results. It can be seen that the solubility diagram of the system Na $_2$ NH $_4$  | SO $_4$ , H $_2$ PO $_4$ ·H $_2$ O at 25° includes six crystallization fields of solid phases, eight lines of three-phase equilibrium, and four invariant points, corresponding to equilibrium of the solution with three solid phases. 11 refs.

**092520 PVTX DATA FOR THE SYSTEM KCl-H $_2$ O IN THE TEMPERATURE RANGE 298.15-573.15 K AND AT PRESSURES FROM EQUILIBRIUM TO 1000 BAR.** Experimentally obtained, precise values for the specific volumes of aqueous salt systems are difficult to employ directly. Difficulties arise because the data are generally obtained using different ranges of the parameters of state, and are reported for particular temperatures, pressures, and compositions that do not permit linear interpolation of the property of interest. These limitations do not apply when there is an equation of state describing the thermodynamic properties. This work attempted to find an equation of state that describes the thermodynamic property with an error relative to the result of experimental precise studies not lower than the requirements of the areas of application indicated above. The requirements can be satisfied by a mathematical description that provides for a deviation from the values of known studies no worse than the experimental error they show. Some of the results are presented in this article. 7 refs.

**092521 SELF-ORGANIZATION OF THE SUPERMOLECULAR STRUCTURE OF CARBOXYMETHYLCELLULOSE IN HIGHLY PURIFIED AQUEOUS SOLUTIONS.** Processes of the spontaneous formation of secondary supermolecular aggregates (equilibrium with the medium of the particles) and anisotropic supermolecular structures of a fluctuation nature which take place in time are observed in highly purified aqueous solutions of CMC in the concentration of 1.2-1.8%. Based on the character of the supermolecular organization of solutions of CMC with a change in the concentration, the liquid crystalline state is not attained due to transition of the solution in the concentration of approximately 7% to the gel state. It is also found that the x-ray structural analysis of solutions in CMC does not reveal any changes in the x-rays in concentration of the solutions up to a concentration of 25%, where the solution is a completely formed film, and confirms the absence of structural changes in the gel with an increase in the concentration of CMC. 8 refs.

**092525 LASER EFFECT OF A SERIES OF VARIOUSLY SUBSTITUTED PYRYLIUM AND THIOPYRYLIUM SALTS.** The laser effect of 47 pyrylium salts and 6 thiopyrylium salts has been investigated by excitation with a pulsed (5 Hz) nitrogen laser (337 nm) and compared to that of rhodamine 6G. The thiopyrylium derivatives as well as the pyrylium salts which contain nitro substituents show a rather poor effect if any. Out of the pyrylium series, 19 compounds have an important response as laser dyes. For most of them, the lasing range is larger than that of rhodamine 6G and for several of them (19, 20, 21, 32, 35, 39, 47 and 46) this range covers more than 80 nm. The behavior of 35 and 47 is particularly striking. (Author abstract) 20 refs.

#### Structure

**092526 CONDUCTIVE TETRAMETHYLTETRASELENAFULVALENIUM SALT BASED ON A DIVALENT OXALATO-BRIDGED BIS-(TETRAFLUOROMETALLATE) COMPLEX: (TMTSF) $_3$ (Ti $_2$ F $_8$ (C $_2$ O $_4$ )).** Single crystals of the salt exhibit a mixed-valence stack with a cylindrical divalent inorganic anion about twice as large as those that typically fit in the classical (TMTSF) $_2$ X structure. The centrosymmetrical unit cell is triclinic. Electrical conductivity measurements show a semiconducting behavior ( $\sigma_{298K} = 0.8 \Omega^{-1} \text{cm}^{-1}$ ). In addition, this is the first report of an X-ray structure determination for the anion Ti $_2$ F $_8$ (C $_2$ O $_4$ ) $^{2-}$ . (Edited author abstract) 14 refs.

Penicaud, A. (CNRS, Orsay, Fr); Batail, P.; Bechgaard, K.; Sala-Pala, J. *Synth Met* v 22 n 3 Jan 1988 p 201-207.

**092527 CRYSTAL STRUCTURES OF AuCl $_2$  SALTS OF BIS(ETHYLENEDITHIO)-TETRATHIAFULVALENE(BEDT-TTF). EXISTENCE OF DIVALENT GOLD, Au(II).** The organic donor BEDT-TTF forms 2:1 and 1:1 salts with AuCl $_2^-$ . The 2:1 salt is the  $\beta'$ -type which is isostructural with the ICl $_2^-$  and IBrCl $^-$  salts, and has one-dimensional electronic structure. In the 1:1 salt, half of AuCl $_2^-$ , which are incorporated in the sheets of BEDT-TTF, are likely to be formally neutral and to include anomalous divalent gold, Au(II). (Author abstract) 17 refs.

Mori, Takehiko (Inst for Molecular Science, Okazaki, Jpn); Inokuchi, Hiroo. *Solid State Commun* v 62 n 8 May 1987 p 525-529.

**092528 STRUCTURE AND PROPERTIES OF SALTS OF CELLULOSE XANTHIC ACID.** The effect of the structure of salts of cellulose xanthic acid on their properties has been examined. It has been shown that the character of the bond between the metal and the dithiocarbonate group in CXA (Cellulose Xanthic Acid) salts

varies gradually as the electronegativity of the metal increases, going from ionic to covalent or coordinate. The degree of ionicity of the metal-sulfur bond exerts a decisive effect of the solubility of metal cellulose xanthates in water or dilute alkali solutions. The heat resistance of CXS salts, and also the rate of acid hydrolysis of the thiocarbonate groups, depend on the degree of ionicity of the sulfur-metal bond, the xanthates of the heavy metals which have a complex structure (copper, silver, cadmium, cobalt, bismuth, and lead) being the most stable. 34 refs.

**092529 4 K CRYSTALLOGRAPHIC AND ELECTRONIC STRUCTURES OF (TMTTF)<sub>x</sub>X SALTS (X<sup>-</sup>:PF<sub>6</sub><sup>-</sup>, AsF<sub>6</sub><sup>-</sup>). The 4 K crystallographic and electronic structures of (TMTTF)<sub>x</sub>PF<sub>6</sub> and (TMTTF)<sub>x</sub>AsF<sub>6</sub> are presented. The structural investigation was performed by neutron diffraction. Thermal expansion and structural data are compared to those of the Se analogs. The tight-binding band electronic structures are based on calculations of the transfer integrals within the dimer splitting approximation. The results are discussed and compared to the room-temperature values. The transfer integrals of the two salts, which are very similar at 300 K, tend to differ markedly at low temperature. The observed differences in the transfer integrals are related to the changes of the orientation of two neighboring organic chains. The variations of the electronic parameters appear to depend on the anion. (Author abstract) 31 refs.**

**092531 STRUCTURE AND PHASE TRANSITIONS OF AROMATIC RADICAL CATION SALTS - A NEW CLASS OF ORGANIC METALS.** Stable radical cation salts of a variety of simple arenes can be prepared by anodic oxidation. These highly conducting crystals are deposited on the anode during the electrocrystallization. They can be considered as a new family of organic conductors built up from simple, easily obtainable building blocks. The packing found between the aromatic rings can be regarded as a model for the interchain interactions in conducting polymers, e.g., doped poly-p-phenylene. The crystal structures of most radical cation salts can be characterized as columnar structures. The molecular overlap plays an important role in the electrical and magnetic properties. (Edited author abstract) 25 refs.

Enkelmann, V. (Max-Planck-Inst fuer Polymerforschung, Mainz, West Ger); Goeckelmann, K. *Ber Bunsenges Phys Chem* v 91 n 9 Sep 1987, Discuss Meet: Phys and Chem, of Unconv Org Mater, Wiesbaden-Naurod, West Ger, Apr 29-May 1 1987 p 950-957.

## Synthesis

**092532 SYNTHESIS, CRYSTAL STRUCTURES AND PHYSICAL PROPERTIES OF CONDUCTING SALTS (BEDT-TTF)<sub>x</sub>X (X = CF<sub>3</sub>SO<sub>3</sub> OR p-CH<sub>3</sub>C<sub>6</sub>H<sub>4</sub>**

SO<sub>3</sub>). Two new conducting BEDT-TTF salts with organic anions, (BEDT-TTF)<sub>x</sub>X, where X = CF<sub>3</sub>SO<sub>3</sub> (1) or p-CH<sub>3</sub>C<sub>6</sub>H<sub>4</sub>SO<sub>3</sub> (2), are described. Crystal data: (1), monoclinic, space group P2<sub>1</sub>/n, a = 6.649(1), b = 33.050(3), c = 15.018(1) Å, β = 90.98(1)°, V = 3299.8 Å<sup>3</sup> and Z = 4; (2), monoclinic, space group P2<sub>1</sub>, a = 7.785(1), b = 6.697(2), c = 34.402(8) Å, β = 91.10(2)°, V = 1793.2 Å<sup>3</sup> and Z = 2. The conductivity of (1) shows two phase transitions at 218 and 306 K and exhibits a temperature-dependent activation energy at all temperatures from 150-400 K. The conductivity of (1) between 220 and 400 K suggests an analogy with the inorganic quasi-one-dimensional material K<sub>2</sub>[Pt(CN)<sub>4</sub>B<sub>2</sub>O<sub>3</sub>·3H<sub>2</sub>O. (2) is semiconducting in the temperature range 150-300 K, σ<sub>300K</sub> = 10<sup>-3</sup> S cm<sup>-1</sup> and E<sub>g</sub> = 0.26 eV. (Author abstract) 8 refs.

## Thermal Conductivity

**092533 THERMAL CONDUCTIVITY OF LiKSO<sub>4</sub> NEAR ITS HIGH-TEMPERATURE PHASE TRANSITION.** The thermal conductivity of LiKSO<sub>4</sub> ferroelastic crystals was measured along the three principal crystallographic axes in the vicinity of its high-temperature phase transition at 705 K. The data showed an anomalous behaviour in the temperature dependence of the thermal conductivity in the transition region of width about 25 K. The anomaly in the phonon contribution to the conductivity was referred to the freezing-in of either optic and/or acoustic modes of lattice vibrations in the near vicinity of the phase transition. The results are discussed in terms of the scattering mechanisms of energy carriers. (Author abstract) 18 refs.

Okaz, A.M. (Alexandria Univ, Alexandria, Egypt); Mahmoud, S.M.; Kassem, M.E. *J Mater Sci* v 23 n 3 Mar 1988 p 998-1001.

## Thermal Effects

**092534 THERMAL STABILITY OF SALTS OF HIGHER QUATERNARY ALKYLAMMONIUM BASES.** The thermal stability of salts of higher quaternary alkylammonium (QAS) bases used as extracting agents for metals in hydrometallurgy was studied by complex thermal analysis and by different chemical methods of determining the degree of decomposition of QAS on heating. The study of the composition of the products of decomposition of QAS at different temperatures revealed that 100°C is the limit temperature for heating the reaction mass in quaternization of higher amines, since the relative thermal decomposition of the salts of higher alkylammonium bases attains 1.5% of the product per h at this temperature. Heating of higher QAS in air at 120-150°C results in irreversible decomposition of QAS, primarily with the formation of unsaturated compounds and amine salts. 7 refs.

Sokal'skaya, L.I.; Semenov, V.A.; Osipova, E.S.; Zhukova, N.G. *J Appl Chem USSR* v 60 n 5 pt 2 May 1987 p 1063-1066.

**Thermal Properties See HEAT PUMP SYSTEMS—Chemical Reactions.**

## Thermodynamic Properties

**092535 HEATS OF FORMATION OF QUATERNARY HYDRAZINIUM SALTS.** For industrial production of N,N-dimethyl-N-benzyl-hydrazinium (I) and N,N-dimethyl-N-(2-chloroethyl)hydrazinium (II) chlorides, data on their heats of formation by given reactions are required. The heat effects ΔH<sub>R</sub><sup>o<sub>1</sub> and ΔH<sub>R</sub><sup>o<sub>2</sub> of two reactions were calculated from literature values of the enthalpies of formation of the original reactants and from the authors' experimental values for the enthalpies of formation of compounds (I) and (II). The final reaction products were analyzed for As<sub>2</sub>O<sub>3</sub>, H<sub>2</sub>PtCl<sub>6</sub>, HCl, and</sup></sup>

HNO<sub>3</sub> contents in order to determine the quantity of heat evolved in side reactions. The standard enthalpies of formation ΔH<sub>f</sub><sup>o of the test compounds were calculated from the values obtained for the enthalpies of combustion and standard enthalpies of formation. The values obtained for the molar enthalpies of combustion ΔH<sub>c</sub><sup>o and enthalpies of formation ΔH<sub>f</sub><sup>o are given. 12 refs.</sup></sup></sup>

## Thermodynamics

**092536 THERMODYNAMICS OF Ca-CaF<sub>2</sub> AND Ca-CaCl<sub>2</sub> SYSTEMS FOR THE DEPHOSPHORIZATION OF STEEL.** Calcium is soluble in halide salts which can be used to remove phosphorus from steel as a phosphide ion. The activity and activity coefficient of calcium phosphide and the equilibrium phosphorus distribution ratio between Ca-CaF<sub>2</sub> and Ca-CaCl<sub>2</sub> fluxes and pure solid iron were measured as a function of the Ca composition in the flux at 1350°C, 1400°C, and 1450°C. The Ca-Ca halide fluxes were equilibrated with pure solid iron and a Ag-Ca alloy under an Ar atmosphere. The Ag-Ca alloy was used to maintain a constant chemical potential of calcium. Phosphorus distribution between these fluxes and solid pure iron increased with increasing calcium activity and decreasing temperature. The activity coefficient of γCa<sub>15</sub>P was 36.6 at 1350°C and 11.0 at 1450°C for a calcium activity of 0.2 (wt pct Ca = 2.5) in the Ca-CaF<sub>2</sub>; the activity coefficient increases with increasing Ca in the flux. In addition, the activity of Ca in the Ca-Ca halide fluxes was determined. The equilibrium phosphorus distribution ratio between Ca-Ca halide systems and molten chromium steel was calculated as functions of Cr and C contents of the metal and calcium activity in the flux at 1600°C. This ratio was about 20 for 18 pct Cr stainless steel at 1600°C. (Edited author abstract). 23 Refs.

## Transport Properties

**092537 COMPLEXATION AND TRANSPORT PROPERTIES IN BINARY GLASS-FORMING MOLTEN CHLORIDE SYSTEMS.** Following a recent study of the contrasting effects of FeCl<sub>4</sub><sup>-</sup> versus CrCl<sub>6</sub><sup>3-</sup> complex anion formation on the transport properties of solutions containing them, we report a study of the intermediate cases of MCl<sub>4</sub><sup>2-</sup> complex formation (M = Co<sup>2+</sup>, Ni<sup>2+</sup>, and Cd<sup>2+</sup>). In these cases an intermediate and unspectacular response is observed, and secondary factors intercede to produce an apparent contradiction between composition-dependent behavior close to, and far from, the glass transition. The contradictions are resolved by recognizing that, in these intermediate cases, the predominant effect of complexation is to produce a decrease in liquid 'fragility'. (Author abstract) 12 refs.

Elias, Anselmo (Univ of Lisbon, Lisbon, Port); Angell, C. Austen. *J Chem Eng Data* v 33 n 1 Jan 1988 p 1-5.

**092538 CORRESPONDING STATES CORRELATION OF TRANSPORT PROPERTIES OF UNIVALENT MOLTEN SALTS.** A law of corresponding states was developed for the transport properties of univalent molten salts with the use of four potential parameters and a characteristic mass. The characteristic mass was defined as m<sub>R</sub> = 2m<sub>A</sub>m<sub>C</sub>/(m<sub>A</sub> + m<sub>C</sub>) or m<sub>S</sub> = {2m<sub>A</sub><sup>1/2</sup>m<sub>C</sub><sup>1/2</sup>}/(m<sub>A</sub><sup>1/2</sup> + m<sub>C</sub><sup>1/2</sup>)<sup>2</sup>, where m<sub>A</sub> and m<sub>C</sub> are anion and cation masses, respectively. The corresponding states correlations were obtained by expanding the autocorrelation functions of the dynamical quantities for the transport properties with the mass difference between the anion and cation. The four-poten-

tial-parameter correlation was applied to the electrical conductivity, viscosity, and self-diffusion coefficient. (Edited author abstract) 17 refs.

## X-Ray Analysis

**092539 X-RAY STUDY OF THE TRIIODIDE CHAIN DISORDER IN SOME IODIDE ORGANIC SALTS.** One-dimensional iodide organic salts often present a similar organization of triiodide chains embedded in an organic matrix. At room temperature, these chains may present an important structural disorder characterized by the absence of long-range order in the chain direction. As the temperature is lowered, order generally develops, leading to an order-disorder phase transition of an original type. It is illustrated on some compounds by x-ray scattering techniques. (Author abstract) 14 refs.

Albouy, P.A. (Univ Paris Sud, Orsay, Fr); Pouget, J.P.; Strzelecka, H. *Synth Met* v 24 n 1-2 Apr 1988, Proc of the Second Fr-Pol Colloq on Low Dimens Org Conduct and Electroactive Polym, Nancy, Fr, May 12-15 1987 p 127-136.

**092542 INVESTIGATIONS OF THE MAGNETIC PROPERTIES AND DEMAGNETIZATION PROCESSES OF AN EXTREMELY HIGH COERCIVE  $\text{Sm}(\text{Co}, \text{Cu}, \text{Fe}, \text{Zr})_{7.6}$  PERMANENT MAGNET. I. DETERMINATION OF INTRINSIC MAGNETIC MATERIAL PARAMETERS.** The intrinsic magnetic material parameters of the 2:17 type matrix phase and the 1:5 type precipitation phase in sintered multiphase  $\text{Sm}(\text{Co}_{0.68}\text{Fe}_{0.22}\text{Zr}_{0.02})_{7.6}$  permanent magnet was determined in the whole ferromagnetic temperature regime between 10 K and  $T_C = 1070$  K. Magnetization curves measured parallel and perpendicular to the alignment axis are analyzed taking into account the volume fractions of ferromagnetic phases, their magnetostatic interactions, and the angular distribution of grain axes. The influence

of annealing treatments on the intrinsic magnetic properties of the relevant ferromagnetic phases are investigated. (Author abstract) 45 Refs.

Durst, K.-D. (Max-Planck-Institut fuer Metallforschung, Stuttgart, West Ger); Kronmueller, H.; Ervens, W. *Phys Status Solidi A* v 108 n 1 Jul 1988 p 403-416.

## Physical Properties

**092543 NONLINEAR FARADAY AND VOIGT EFFECT IN A  $J=1$  TO  $J'=0$  TRANSITION IN ATOMIC SAMARIUM VAPOR.** Nonlinear modifications of the Faraday- and Voigt effect are observed in the atomic  $^{152}\text{Sm}$   $\gamma=570.68$  nm  $^7F_1-^7F_0$  line due to optically induced Zeeman coherence and optical pumping effects in the  $^7F_1$  Sm ground state. The magneto-optical signals display narrow spectral structures when the external longitudinal or transverse magnetic field is scanned through zero; over a wide angle the amplitudes of the magneto-optical signals show a cubic dependence on laser intensity. Our observations agree with a simple model based on a perturbation treatment for an atomic  $J=1$  to  $J'=0$  transition. (Edited author abstract) 15 refs.

**Spectroscopic Analysis** See Also FLUORESCENCE.

**092545 DISCRIMINATION OF  $\text{Sm}$  CENTERS IN  $\text{ZnS}$  BY SITE SELECTIVE LASER SPECTROSCOPY.** Evidence of seven Sm centers in a  $\text{ZnS:Sm}$ , Li crystal has been found. The relative emission intensities due to different centers depend on exciting laser power. The coupling of the excited states of the rare earth ions to the quasi-continuum of states of the whole complex, where DA pairs may be a part of it, is responsible for the different excitation probabilities observed. 3 refs.

**092546 INTERACTION OF  $\text{Sm}^{3+}$  IONS IN BORATE GLASS.** The interaction of  $\text{Sm}^{3+}$  ions in borate glasses doped with different concentration has been investigated. The decay curves become nonexponential when the  $\text{Sm}^{3+}$  concentration is larger than 1 mol%. It can be explained by cross relaxation between  $\text{Sm}^{3+}$  ions. By fitting the experimental data to the model of Inokuti and Hirayama, the cross relaxation has been assigned to be of electric dipole-dipole character (EDD). According to Dexter's theory, the transfer probabilities for four pairs of possible cross relaxation were estimated. The intensity parameters of  $\text{Sm}^{3+}$  in borate glass, which are used in the estimation of transfer probabilities, were calculated by the use of emission spectra. (Author abstract) 5 refs.

**092547 GALVANOMAGNETIC EFFECTS IN  $\text{Sm-Co}$  AMORPHOUS MAGNETIC FILMS.** Galvanomagnetic effects in  $\text{Sm-Co}$  amorphous magnetic films are discussed. In films with in-plane magnetization, resistivity rose gradually with the Sm concentration, while the Hall resistivity, Hall sensitivity, and Hall voltage peaked around 15 atm% Sm and gradually declined. In perpendicular magnetization films, both the Hall resistivity and Hall sensitivity decreased as the Sm content increased. In both perpendicular and in-plane magnetization film, the Kerr rotation angle decreased as the Sm concentration increased. 3 refs.

## Synthesis

**092548 STRUCTURE FORMATION IN ALLOYS OF THE SAMARIUM-COBALT SYSTEM OBTAINED BY THE DIRECT-REDUCTION METHOD.** The existence of  $\text{Sm}_2\text{Co}_{19}$  phases in powders obtained by both the direct-reduction method and by crushing ingots of an alloy of the pure components is reliably established. It is shown that during the diffusion of samarium into the cobalt particles the formation of  $\text{Sm}_2\text{Co}_7$  and  $\text{Sm}_2\text{Co}_{19}$  phases is preceded by a state of short-range ordering of the shear planes. It is ascertained that the radial crystalline texture in the outer layers of the powder obtained by direct reduction coincides with the 001 direction of the lattice, and an assumption is made concerning the mechanism of formation of this texture. On the basis of a comparative phase analysis of the compositions of the powders obtained by the two methods, it is established that alloys obtained by reduction are closer to a two-phase state than ingots of alloys of the pure components. ## Magnetic Properties

**092549 HARD MAGNETIC PROPERTIES OF THE RAPIDLY QUENCHED  $\text{Sm}(\text{Co-Fe-B})_5$  ALLOY RIBBONS.** The structure and hard magnetic properties of the rapidly quenched  $\text{SmCo}_{5-x}\text{B}_x$  ( $0 \leq x \leq 1$ ) and  $\text{Sm}(\text{Co}_{1-x}\text{Fe}_x)_2\text{B}$  ( $0 \leq x \leq 0.74$ ) alloy ribbons fabricated under various quenching rates were systematically examined. Metastable states, such as  $\text{CaCu}_2$  type disordered structure and amorphous state were found in a wide composition range,  $0.6 \leq x \leq 1.0$  for  $\text{SmCo}_{5-x}\text{B}_x$  and  $0 \leq x \leq 0.5$  for  $\text{Sm}(\text{Co}_{1-x}\text{Fe}_x)_2\text{B}$  in the ribbons fabricated under high quenching rate. The maximum value of  $H_c$  ( $> 18 \text{ kOe}$ ) was obtained for ribbons which consist of the  $\text{CaCu}_2$  disordered structure as a single phase. It was concluded that the formation of  $\text{CaCu}_2$  type disordered  $\text{Sm}(\text{Co-Fe-O})_5$  compound with high Fe and low B content was considered to be effective to improve the hard magnetic properties of  $\text{Sm-Co}$  based alloys. (Edited author abstract) 5 refs.

## SAMARIUM COBALT IRON COPPER ALLOYS

## Magnetic Properties

**092550 EFFECTS OF Zr CONTENT ON PHASE TRANSFORMATION AND MAGNETIC PROPERTIES OF  $\text{Sm}(\text{Co}, \text{Cu}, \text{Fe}, \text{Zr})_{7-9}$  MAGNET ALLOYS.** Sm-Co-7.0 at%Cu-22.0 at%Fe- (0.1, 4.2, 0 and 3.0 at%) Zr sections of the phase diagram were determined in the Sm content range from 6 to 16 at% above 1073 K. Addition of Zr by 1.4 or 2.0 at% expands the Sm solubility in the 2/17 phase towards both the richer and poorer side and changes the crystal structure to  $\text{TbCu}_7$  and/or  $\text{Th}_2\text{Ni}_{17}$  type at high temperature. Addition of Zr by 3.0 at% expands the (2/17+2/7) phase region which has the  $\text{TbCu}_7$  and/or  $\text{Th}_2\text{Ni}_{17}$  type structure(s).  $\text{Sm}(\text{Co}, \text{Cu}, \text{Fe}, \text{Zr})_2$  alloys possess high coercivity when homogenized with  $\text{TbCu}_7$  (Zr 1.4 and 2.0%) at high temperature and decompose into the 2/17 phase with  $\text{Th}_2\text{Ni}_{17}$  type structure and 1/5 phase with  $\text{CaCu}_5$  type structure by aging treatment. (Edited author abstract) 15 refs. In Japanese.

## SAMARIUM COBALT ZIRCONIUM ALLOYS

**092551 CELLULAR MICROSTRUCTURE DEVELOPMENT IN  $\text{Sm}(\text{Co}, \text{Fe}, \text{Cu}, \text{Zr})_{8.35}$  ALLOYS.** TEM studies of Zr-containing 2:17-type permanent magnet alloys show that the cellular microstructure develops from a high temperature 2:17R phase, first by the precipitation of Sm-depleted, Zr-rich '2:17H' platelet phase, then by the precipitation of Cu-rich, Fe- and Zr-depleted '1:5' boundary phase. These results are supportive of, but also suggest refinements to, a model proposed earlier for the metallurgical behavior of these alloys. (Author abstract) 14 refs.

Ray, A.E. (Univ of Dayton, OH, USA); Soffa, W.A.; Blachere, J.R.; Zhang, B. *IEEE Trans Magn* v MAG-23 n 5 Sep 1987, INTERMAG '87: Int Magn Conf, Tokyo, Jpn, Apr 14-17 1987 p 2711-2713.

## Magnetic Properties

**092552 EFFECT OF ZIRCONIUM ON STABILIZATION FOR THE 1-7 PHASE IN 2-17 TYPE Sm-Co PERMANENT MAGNET.** The 2-17 type rare earth permanent magnets show high coercivity only when they are subjected to aging after solution treatment. It is necessary for obtaining high coercivity that they are in a single 1-7 phase region at the solution temperature. In the present study, an isothermal phase diagram in the Sm-Zr-Co ternary system at 1473 K close to the solution temperature was constructed in order to investigate the extent of composition ranges stable for the 1-7 phase due to Zr addition. The behavior of the Zr atom in the 1-7 phase was investigated. The Zr addition may extend the stable 1-7 phase region to a higher Co content. Zr atom dissolved in the 1-7 phase seems to substitute either a pair of Co atoms occupying a dumbbell site or a single Sm atom involved in the 1-7 phase. (Edited author abstract). 14 Refs. In Japanese.

**092553 INFLUENCE OF ZIRCONIUM ON  $\text{Sm}(\text{Co}, \text{Fe}, \text{Cu}, \text{Zr})_{7.2}$  ALLOYS FOR PERMANENT MAGNETS. II: COMPOSITION AND LATTICE CONSTANTS OF THE PHASES IN HEAT-TREATED MATERIALS.** Specimens of composition  $\text{Sm}(\text{Co}_{0.69}\text{Fe}_{0.22}\text{Cu}_{0.06}\text{Zr}_{0.03})_{7.2}$  were submitted to either long

annealing at 1160-850°C or heat treatments similar to those applied to magnetic materials. The composition and lattice constants of the phases in the specimens were determined by electron-probe analysis and X-ray diffraction. Under equilibrium conditions, a mixture of 2:17R, 2:17H, 2:7 is stable at 1160-1000°C. At 850°C, a mixture of 2:17R, 2:7R, 5:19 is found. Apart from these phases, a 1:3 phase is present in specimens treated like permanent magnetic alloys. Iron is mainly distributed in 2:17, copper replaces cobalt in 2:7, zirconium replaces samarium and induces the precipitation of phases of the series  $\text{Sm}_{n+1}\text{Co}_{5n-1}$ , at the expense of 1:5. The higher the zirconium content, the lower the n of the phase precipitated. (Edited author abstract) 21 refs.

## Magnetic Properties

**092555 MAGNETIC PROPERTIES OF  $\text{SmMn}_2\text{Ge}_2$  COMPOUNDS.** The magnetic characteristics of  $\text{SmMn}_2\text{Ge}_2$  compounds have been studied by measurements of ac susceptibility, magnetization, electrical resistivity and X-ray diffraction; the p-T diagram has also been determined. With decreasing temperature the phase transitions occur in the following sequence, ferromagnetism is observed in the temperature region of 153 K < T < 341 K, antiferromagnetism becomes stable for 106.5 K < T < 153 K and re-entrant ferromagnetism appears below 106.5 K. The observed magnetic phase transitions correspond with the change of the lattice parameters. In the antiferromagnetic phase the magnetic field  $H \approx 6$  kOe induces the transition into the ferromagnetic phase. The pressure dependence of the phase transition temperatures was also observed. (Author abstract). 12 Refs.

## Synthesis

**092558 SYNTHESIS AND STRUCTURAL STUDY OF SAMARIUM HEXACYANOFERRATE (III) TETRAHYDRATE,  $\text{SmFe}(\text{CN})_6 \cdot 4\text{H}_2\text{O}$ .** Single crystals of  $\text{SmFe}(\text{CN})_6 \cdot 4\text{H}_2\text{O}$  prepared from an aqueous solution under ambient conditions have been used for single-crystal diffraction, thermal gravimetric analysis, and infrared spectrometric studies. This characterized compound is compared to previously reported  $\text{LnT}(\text{CN})_6$  (T = Cr, Fe, Co) structures. Samarium hexacyanoferrate (III) tetrahydrate is found to be monoclinic, not hexagonal or orthorhombic as presupposed.  $\text{SmFe}(\text{CN})_6 \cdot 4\text{H}_2\text{O}$  crystallizes in space group  $\text{P2}_1/\text{m}$  (No. 11),  $a = 7.431(1)$ ,  $b = 13.724(3)$ ,  $c = 7.429(2)$  Angstrom,  $\beta = 119.95(1)^\circ$ ,  $Z = 2$ . Full-matrix least-squares refinement has yielded the final values of  $R = 0.0292$  and  $R_w = 0.0296$  for 1028 unique reflections. The observed and calculated densities are 2.198(3) and 2.197  $\text{Mg m}^{-3}$ , respectively. (Edited author abstract) 20 refs.

**092562 COMPOSITE OPERATING CHARACTERISTICS OF SAMPLING SYSTEMS WITH RULES OF SEVERITY ADJUSTMENT AND DISCONTINUING INSPECTION.** A key to the analysis of composite operating characteristics of sampling systems having normal, tightened, and reduced plans together with an entire switching procedure involving discontinuing inspection lies in determining the expected proportion of the lots inspected under the various plans. Traditional means employed in such cases are the methods of Markov chain or computer simulation. In this paper, an expression of the expected proportion of lots inspected under various plans is developed by using the method of a uni-variable generating function, a departure from the traditional methods mentioned above. As the discontinuing inspection can be switched to other objects of inspection, the composite operating characteristics of the sampling system are studied with rules of severity adjustment and discontinuing inspection. (Edited author abstract) 5 refs. In Chinese.

Tang, Guoqing; Zhang, Weiji. *Bingong Xuebao* v 2 n 3 Aug 1987 p 66-72.

**092563 RAPID GENERATION OF FREQUENCY TABLES.** This paper is concerned with situations where random samples of size  $n$ , from a discrete distribution, are required in the form of frequency tables rather than as streams of  $n$  individual variables. Instead of constructing each table by generating  $n$  observations and collecting them together, each table is generated directly by regarding it as a single sample from a multinomial distribution whose index is  $n$  and whose probabilities are those of the target distribution placed in decreasing order of magnitude. Sampling is achieved by a series of conditional binomial generations using a fast 'variable-parameter' algorithm. Results are presented which show that the new direct procedure is generally far faster than the standard indirect procedure using the very fast alias method to generate individual observations. Extensions to bivariate discrete distributions and to continuous distributions are noted. (Edited author abstract) 13 refs.

**092564 MUTUAL INFORMATION, ESTIMATION IN THE SAMPLING WITHOUT REPLACEMENT.** The aim of the present paper is to approach the value of the mutual information of order  $\beta=2$  in a large population on the basis of a sample drawn at random and without replacement from it. This purpose is achieved by obtaining an unbiased estimator of that value and estimating its mean square error. In addition, a contrast between samplings with and without replacement shows that the second one entails an improvement in the estimation precision with respect to the first one. Finally, we discuss the suitability of adopting the measure of order  $\beta=2$ . (Edited author abstract) 39 refs.

Gil, Maria Angeles; Perez, Rigoberto; Gil, Pedro. *Kybernetika* v 23 n 5 1987 p 407-419.

**092565 ZERO ACCEPTANCE SAMPLING PLANS: EXPECTED COST INCREASES.** The cost of sampling has led practitioners and researchers to search for sampling procedures that require small sample sizes, but still afford adequate consumer and producer protection. The zero acceptance number single sampling plans proposed by N.L. Squeglia were meant to provide equal or greater consumer protection with less inspection than the corresponding MIL-STD-105D sampling plans. Practitioners who are being pressured to use  $C=0$  acceptance sampling plans to leave the impression of total conformance to product specifications should exercise extreme caution. If one were to use the Squeglia  $C=0$  plans, unless the true process percent defective is substantially better than the specified AQL, total inspection cost will be significantly higher. 7 refs.

Baker, R.C. (Univ of Texas, Arlington, TX, USA). *Qual Prog* v 21 n 1 Jan 1988 p 43-46.

**092566 SAMPLING PLAN.** A computer program is developed to construct sampling plans based on the binomial distribution. The paper assumes prior knowledge of acceptance sampling concepts and presents a computer program written in BASIC on IBM PCXT for this purpose.

**092567 SAMPLING THEOREM AND WINTNER'S RESULTS ON FOURIER COEFFICIENTS.** The present paper arises from the reconsideration, aimed towards a sampling theorem, of a book on Fourier series by A. Wintner. The idea of this book was to obtain precise formulae for the Fourier coefficients of a function from a countable set of its values on the unit circle. 9 Refs.

Schiff, J.L. (Univ of Auckland, Auckland, NZ); Walker, W.J. *J Math Anal Appl* v 133 n 2 Aug 1 1988 p 466-471.

**092568 ANTI-THETIC-VARIATE SPLITTING FOR STEADY-STATE SIMULATIONS.** Obtaining precise estimates of parameters of infinite-horizon or steady-state simulations can be expensive because of the need to discard initial outputs to mitigate the effects of initial condition. We consider splitting independent replications at the point of output truncation into dependent replications to reduce point estimator variance and/or simulation cost. The results indicate that antithetic-variate splitting can be more effective than the classical antithetic-variate estimator in steady-state simulations where antithetic sampling is effective. It is essential to design the simulation experiment so that negative correlation induced between processes is preserved in the output processes. Three key factors in the design are: method of input process generation; synchronization of random number streams; and monotonicity of the input-output transformations. (Edited author abstract) 14 Refs.

Nelson, Barry L. (Ohio State Univ, Columbus, OH, USA). *Eur J Oper Res* v 36 n 3 Sep 1988 p 360-370.

**092569 COMETARY DUST SIZING: COMPARISON BETWEEN OPTICAL AND IN-SITU SAMPLING TECHNIQUES.** We try to evaluate the level of

confidence that can be placed in the optical methods available for sizing cometary dust (and, at the same time, deriving all its other characteristics). We use for this purpose the new informations provided by the in-situ sampling of Comet Halley dust. We try to determine whether data from this origin are compatible with visible and I.R. spectra of this comet acquired from the Earth, and with earlier interpretations of such spectra. We find that, as happens frequently when remote sensing and local sampling techniques data can be compared, none of these techniques can claim to be fully satisfactory. In the case of cometary dust, current estimates based on optical sizing only may be much less accurate than previously assumed. Improvements in the observational approaches appear needed, as well as new laboratory investigations and theoretical developments to improve the capabilities of the optical studies of cometary dust. (Author abstract) 40 Refs.

**092570 SELECTIVE SAMPLING METHOD MADE EASY.** While in the usual form of the selective sampling method a speed converter is required, we propose here a version, called blind sampling, which involves only time delays, gates and scalars. Apart from its simplicity, it also allows us to use shorter measuring times. An intermediate arrangement (one-eyed sampling), which shares the advantages of both the lucid and the blind versions, is also explained. A detailed description of the necessary electronic arrangements can be found in Rapport BIPM-85/14, and we plan to publish some recent developments in an appropriate journal. (Author abstract)

Mueller, Joerg W. (Bur Int des Poids et Mesures, Sevres, Fr). *Appl Radiat Isot* v 38 n 10 1987, Tech in Radionuclide Metrol, Proc of an ICRM Semin, Rome, Italy, Jun 15-16 1987 p 885.

**092571 RISK-WEIGHTED STRATEGY OF STATISTICAL SAMPLING.** Traditionally, sampling plans have been based either on randomized sampling or have relied on best engineering judgment. Here, a new strategy is proposed using differences in the risks associated with different units of the sampling set (e.g., a waste barrel, a unit surface at a work or contamination site) to influence the frequency of sampling. This results in a sampling plan which, unlike conventional random sampling, can form the basis for tests involving risk considerations. Sampling rates are higher for units which pose a higher risk, while maintaining a sufficient rate for units with a much smaller risk. This strategy is presented here in a general form and examples are given in the area of transport and disposal of nuclear waste. (Author abstract) 6 refs.

**Analysis** See Also CLAY—Consolidation.

**092572 SAMPLING VARIANCE: BIAS AND REPRODUCIBILITY.** Product quality necessitates the collection of a representative sample for analysis. The representativeness of a sample is measured by its accuracy or variance. Sampling variance is discussed in two parts, bias and reproducibility. Bias is an error that consistently results in either high or low analysis. Test methods for bias are described in detail. Reproducibility is a measure of expected fluctuation around the true result. Reproducibility can be reduced by additional increments, analysis, or both. (Author abstract)

### Mathematical Models

**092574 IMPLEMENTATION OF STRATIFIED SAMPLING FOR MONTE CARLO APPLICATIONS.** Stratified sampling is a method used in Monte Carlo calculations to take advantage of certain known aspects of probability distributions. The sampling region is subdivided into discrete subregions, and each of these is sampled a preassigned number of times. A form of stratified sampling has been implemented into a major Monte Carlo particle transport computer code with very encouraging results. (Author abstract) 12 refs.

**Optimization** See Also WATER RESOURCES—Management.

**092575 OPTIMUM SAMPLING PLANS BASED ON POST-QUALITY CONTROL RELIABILITY.** The effect of variables sampling quality control (QC) on the probability distributions of controlled variables is considered. The resultant filtration effect is shown to be a factor in the determination of post-QC reliability for components, etc., defined by the above variables. A cost optimization procedure is suggested, balancing extra cost of sampling and rejection against reduced cost of failure or defect, leading to the possibility of determining an optimum sampling plan for a given application. ### Planning

**092576 OPTIMAL BAYESIAN SINGLE-SAMPLING ATTRIBUTE PLANS WITH MODIFIED BETA PRIOR DISTRIBUTION.** In this article we study the properties of the optimal Bayesian single-sampling plans when the prior distribution of the lot fraction defective is modified Beta, which has been found useful in the analysis of inspection schemes for complex production systems. These properties are used to devise an improved and more efficient algorithm for the determination of the optimal sampling plans. Numerical examples are presented to illustrate the potential computational savings of the algorithm. (Author abstract) 23 refs.

**092579 COUNTERMEASURE FOR SAND LIQUEFACTION: 'GRAVEL DRAINS METHOD'.** The gravel drain method aims to prevent sandy soil from liquefying by constructing gravel piles in the ground to disperse pore water pressure caused when an earthquake occurs. In designing gravel drains, adequate evaluation of the soil constant and the selection of a highly permeable, choke free gravel are important. The authors propose a selection standard after having made experimental studies. A compaction rod type machine for the construction of gravel drain piles causes low levels of vibration and noise and will not disturb the peripheral ground during its use. 14 refs.

**092580 PROCESSES PRODUCING NORTH AMERICA'S EAST COAST SAND AND GRAVEL RESOURCES: A REVIEW.** Requirements for large volumes of aggregate exist and are expected to expand. Marine deposits of sand and gravel are one such source. The Continental Shelf off the east coast of North America is largely covered by subthoquartzitic to arkosic sands with a few isolated gravel deposits. Coastal processes, which are largely responsible for the form and character of granular sediments in this region are discussed. 160 refs.

**092581 ANALYTICAL AND MODEL STUDIES OF REINFORCEMENT OF A LAYER OF GRANULAR FILL ON A SOFT CLAY SUBGRADE.** The effectiveness of geogrid reinforcement, placed at the base of a layer of granular fill on the surface of soft clay, has been studied by small-scale model tests in the laboratory. In the tests, monotonic loading was applied by a rigid footing, under plane strain conditions, to the surface of reinforced and unreinforced systems, using a range of fill thicknesses and

subgrade strengths. Continuous measurements were made of footing load and footing displacement, and deformations of the subgrade and of the geogrid reinforcement were measured from photographs. From these measurements the different mechanisms of failure in the unreinforced and reinforced system were established. A finite element computer program has been specially formulated to allow inclusion of a thin reinforcing layer, and to handle correctly the large deformations and strains induced in the physical models. (Edited author abstract) 16 refs.

**092582 EFFECTS OF REINFORCING ELEMENTS ON THE BEHAVIOR OF WEAKLY CEMENTED SANDS.** Plane strain test results from weakly cemented sand samples with various types of reinforcement inclusions are reported. Mesh and anchored fibre types of reinforcements are shown to more than double the plane strain shear strength of a 33:1 sand-cement mixture. Other types of inclusions were not as effective, with some actually producing a strength decrease. All inclusions increased the ductility of this weakly cemented sand, allowing the material to absorb strains of 4-6 percent rather than the 0.5-1 percent of failure strain in the unreinforced material. The application of reinforcements to cemented tailings used for mine backfill is briefly discussed. (Author abstract) 3 refs.

### Anisotropy

**092583 EFFECTS OF INITIAL ANISOTROPIC FABRIC AND  $\sigma_2$  ON STRENGTH AND DEFORMATION CHARACTERISTICS OF SAND.** A laboratory investigation has been carried out into the effects of initial anisotropic fabric and  $b = (\sigma'_2 - \sigma'_3) / (\sigma'_1 - \sigma'_3)$  on the strength and deformation characteristics of air-pluviated Toyoura sand. Drained tests in triaxial compression ( $b = 0.0$ ), in plane strain compression ( $b = 0.2$  approximately) and in triaxial extension ( $b = 1.0$ ) were performed at different directions of principal stresses with respect to the deposition direction. The strength in triaxial extension was found to be strongly influenced by failure modes. The inherent anisotropy in strength and the effects of both the parameter  $b$  and the failure mode on strength are portrayed in the form of a three dimensional surface. (Edited author abstract) 28 refs.

### Cleaning

**092584 OPERATING EXPERIENCE ON THE ALLJIG AIR-PULSE GRAVEL JIG FOR SEPARATION OF ORGANIC IMPURITIES IN GRAVEL AND SAND.** Increasing requirements of quality demanded by customers and a worsening of raw-material properties have led to an increased demand for high-performance, economical sorting equipment for gravel and sand processing. The Alljig jigs, which have previously been predominantly used for cleaning coal and other mineral raw materials have also proved reliable for separating organic impurities from gravel and sand. The operating results presented in this paper show that the use of these air-pulsed jigs enables gravel and sand to be produced virtually free of wood and coal at high specific throughputs over the entire grain range 0-32 mm. The utilization of this technique results in significant simplification of processing and plant engineering at gravel preparation plants, so that the economy of using Alljig gravel jigs is achieved extremely rapidly. 4 Refs.

**Compaction** See Also PILES—Design.

**092585 LIQUEFACTION-INDUCED COMPACTION AND SETTLEMENT OF SAND DURING EARTHQUAKES.** By employing a dozen of irregular time histories of motions obtained during the recent major earthquakes, two series of simple shear tests, one in uni-directional and the other in multi-directional loading conditions, were carried out on saturated loose, medium dense and dense samples of Fuji river sand. Following the undrained application of irregular loads, the generated pore water pressures were made to dissipate and the volumetric strains measured. The amount of reconsolidation volumetric strains thus determined is regarded as representing the settlement characteristics of sand which takes place in-situ deposits following the liquefaction during earthquakes. The test results indicated that the magnitude of maximum shear strain induced during the irregular loading is uniquely correlated with the volumetric strains during the reconsolidation. (Edited author abstract) 15 refs.

**Consolidation** See Also AIRPORTS—Construction.

**092586 LIQUEFACTION STRENGTH OF SANDS SUBJECTED TO SUSTAINED PRESSURE.** Using two kinds of sands, a series of cyclic undrained triaxial tests was performed on loose and dense specimens subjected to different periods between 0.1 hour and 68 days of sustained pressure. At the same time, tests on specimens over-consolidated with an OCR of two or four were performed in order to compare the effects of long-term consolidation and over-consolidation. For each sand, the strength increase after 68 days under sustained pressure was found to be equivalent to that due to over-consolidation with an OCR of about two. It was further found that for each sand the strength increase due to long-term consolidation and over-consolidation was found to be a similar function of the plastic axial strain which had occurred during each consolidation history. This result suggests that strength increase by these different consolidation histories is due to a similar mechanism. (Edited author abstract) 10 refs.

**Creep** See ICE—Creep.**Crushing and Grinding**

**092587 MORE RECENT DEVELOPMENTS IN THE FIELD OF GRAVEL CRUSHING.** Reduction is an almost imperative procedure during extraction and treatment of mineral raw materials. The layout of any reduction equipment has to take duly into account the unseverable nexus between raw material, reactor, and operational conditions. Another requirement to be met is market demands. Furthermore energy expenditure and wear behaviour are critical factors for the selection of reduction equipment. Suitable machines to comminute gravel are in the first line cone crushers and impact crushers where some remarkable improvements have been achieved in the recent past. (Author abstract) 6 refs.

**Deformation**

**092588 SOIL PARAMETERS FOR DEFORMATION ANALYSIS OF SAND MASSES.** Meaningful stress and deformation analysis of soil structures requires an adequate stress-strain law. Herein are presented guidelines for selection of parameters for a simple incremental hyperbolic stress-strain law for sand based upon a tangent stiffness that varies with stress level. The parameters are obtained from an examination of laboratory and field

measurements available in the literature, and are presented in terms of both penetration value and relative density. The laboratory results indicate the importance of first-time or primary loading versus repeated loading on modulus values. Back analysis of field observations for monotonic loading conditions indicates that primary loading modulus values obtained from triaxial tests are appropriate at low relative density, whereas perhaps higher values, in the repeated loading range, are appropriate at high relative densities. (Author abstract) 23 refs.

**092589 SYMMETRY OF PEBBLE-DEFORMATION INVOLVING SOLUTION PITS AND SLIP-LINEATIONS IN THE NORTHERN ALPINE MOLASSE BASIN.** Deformation features on pebbles of the Alpine Molasse Basin are most clearly developed in carbonate components. Ductile distortion is small; most of the pebbles moved against each other to produce solution pits and slip-lineations on the pebble surfaces. The complete lineation field has a triaxial geometry. From a compressional axis of divergence with maximum solution, fields of diverging lineations extend to meet at a plane of convergence. Their ends bend away from an intermediate axis towards an (extensional) axis of convergence. The strain-symmetry is pure shear for orthogonal lineation-field axes, uniaxial compression and extension representing special cases. The angle  $\alpha$  between the divergent and the convergent axes decreases from 90 to 0° with the transition from pure to simple shear. Additional aspects of the subject are discussed. (Edited author abstract) 45 refs.

**092590 BIOLOGICAL EFFECTS OF MARINE SAND MINING AND FILL PLACEMENT FOR BEACH REPLENISHMENT: LESSONS FOR OTHER USES.** The U.S. Army Corps of Engineers and others have monitored and evaluated the disruption and recovery of the physical and biological environment during beach replenishment operations. While primary focus has been on beach areas where the material is deposited, borrow areas from which the material has been taken have also been examined. Currently, replenishment material is obtained from new channel construction, dredging operations, nearshore and inshore borrowing. Based on what is known about the biological impacts of beach nourishment and nearshore borrow areas, nearshore and offshore mining operations should not create long-term adverse impacts on organisms and physical characteristics in the area if appropriate site selection, timing, techniques, and monitoring are carefully performed. (Edited author abstract) 9 refs.

**Drying**

**092593 TECHNOLOGICAL SAND DRYING, COOLING, AND PNEUMATIC TRANSPORTATION LINE.** Production trials have been carried out at the Parkhomenko Engineering Works in Voroshilovgrad on an automated technological line for the fluidized-bed drying and cooling of quartz sand, based on the Polish Model Sch5A equipment. The line units comprise equipment for receiving, drying and cooling the sand and a pneumatic transport system which takes the dried sand to supply bunkers in the sand preparation shops, which include a section for the preparation of liquid sand suspensions (ZhSS). The line throughput is 8 tonnes/hr. The paper concludes by emphasizing how the introduction of the technological sand drying, cooling and pneumatic transportation line has eliminated arduous manual labor, improved the health and hygiene aspects of the working conditions, reduced dust pollution in the plant, stabilized the molding and coremaking processes and enhanced the quality of the castings.

**092595 RAIL-AND SEA-BORNE AGGREGATES FOR THE SOUTH-EAST.** The South East Economic Planning Region is made up of the counties that surround Greater London. In 1986 this region consumed 58 million tonnes of aggregate and is forecast to have a demand of 68.9 million tonnes of aggregate in the year 2001. Four major sources of supply go to satisfy the region's current demand. There is the indigenous land-won sand and gravel that until the mid-sixties represented the major part of the region's supply. There is marine aggregate which has increased its contribution since the early fifties. Rail-borne material has also increased its contribution since the early 1970s. Finally, sea-borne material has made a small but steady contribution to the region over the years and is likely to make an increasing contribution in the future.

Tidmarsh, David (Foster Yeoman Ltd). *Quarry Manage* v 15 n 2 Feb 1988 p 31-33.

**Erosion**

**092596 LABORATORY INVESTIGATION OF DUNE EROSION.** A set of laboratory experiments have been conducted to study the relationship between the swash hydrodynamics, height, and velocity, and the quantity of dune eroded due to a single swash. The erosion

at the toe of the dune has been correlated with the force exerted on the dune by the uprush. This erosion-versus-force relationship is based on laboratory tests for a simple sand distribution and moisture content. The test results presented here, as well as recent field experiments, suggest that it is possible to estimate dune erosion by an analysis of the wave swash characteristics. 9 refs.

## Failure

**092597 FAILURE STATE OF A SAND IN SIMPLE SHEAR.** In this article, results of tests on loose and dense Leighton Buzzard sand from two specially instrumented simple shear devices - Cambridge University's device and a Norwegian Geotechnical Institute type - are used to interpret the failure mode and the failure stress state. The data were obtained from the centre of the samples, a region removed from stress concentrations. Failure was observed to be initiated on vertical planes and occurred very soon after shear displacement was applied. However, neither these vertical planes nor the horizontal planes were the planes of maximum stress obliquity mobilized during the tests. (Edited author abstract) 16 Refs.

## Freezing

**092598 FROST PENETRATION AND THERMAL REGIME IN DRY GRAVEL.** The depth of frost and ground temperatures were monitored on a regular basis between 1983 and 1985 at 12 locations in Tumbler Ridge, British Columbia. The soil is dry gravel which has a moisture content of 1.5 to 4 percent. The maximum depth of frost recorded was 3.98 m for a winter having 1,430° C-days. Back calculation using the Stefan equation yielded  $n$  factors relating air and ground freezing indices to be generally within the range of those quoted in the literature. However, in heavily traveled cleared roadways, the value of  $n$  was higher than that reported in the literature. Values of unfrozen thermal diffusivity were calculated from both the temperature dissipation with depth and the time lag that the maximum temperature was recorded with depth. The results of these analyses compare well with typical values quoted in the literature for dry gravel. (Author abstract) 3 Refs.

## Heat Transfer

**092599 ANALYSIS OF THE HEAT STORAGE PROCESS IN WET SOIL SOLVED AS A COUPLED PROBLEM.** A quantitative analysis of the heat storage process is tried in wet sand, based on the simultaneous heat and moisture transfer equations. And the effects of moisture on heat transfer are calculated according to the various moisture contents and mean temperatures of the storage media. The results show that moisture content in soil has considerable effects on heat transfer. The effects depend mainly on the direct effect on thermal conductivity. The contribution of moisture flow to heat diffusion is not so large. It is shown that governing equations can be solved with the linearized approximation except for the case of a high heating temperature or a very low moisture content. (Edited author abstract) 12 refs.

## Mechanical Properties See Also OIL WELL DRILLING.

**092600 ELASTOPLASTIC CONSTITUTIVE MODEL FOR CYCLIC BEHAVIOR OF SANDS.** The constitutive model of sands is proposed to describe the characteristics of plastic behavior for cyclic loadings. A non-associated flow rule is used and both yield function and plastic potential are generalized forms of the Modified Cam clay model. The hardening parameter is represented by the plastic work related to different portions of volumetric and deviatoric changes. The boundary surface is employed to describe the plastic strain within the yield surface. The directional independency of yield condition in triaxial compression and extension tests is extended to that in general stress states. Several drained and undrained cyclic tests are predicted and the comparison is made with experimental results. (Edited author abstract) 23 refs.

Hirai, Hiroyoshi (Kumamoto Univ, Kumamoto, Jpn). *Int J Numer Anal Methods Geomech* v 11 n 5 Sep-Oct 1987 p 503-520.

**092601 MODELING GROUTED SAND UNDER TORSIONAL LOADING.** Chemically grouted sand is considered a two-phase particulate composite, and the mechanical properties under pure torsional loading are examined at both the particulate and composite levels. Both the adhesive and cohesive properties of grout are believed to influence the behavior of grouted sand, and an experimental program was conducted to quantify the particular relationship for each. These data, together with the porosity of the sand, are employed to formulate strength, shear modulus, and failure strain models for predicting the behavior of grouted sand from a knowledge of the properties of the constituents. The most critical mode of failure for grout and grouted sand is tension, but comparisons are also made between the shear and compressive properties. (Edited author abstract) 9 refs.

**092602 USE OF CRITICAL STATE REPRESENTATIONS OF SAND IN THE METHOD OF STRESS CHARACTERISTICS.** The limitations of critical state representations of sand behavior are discussed and it is shown that stress dilatancy is an implicit part of a critical state framework. It is then argued that dilatancy leads to underestimates of bearing capacity factors in the method of characteristics. Kinematic constraints should also be considered in such calculations. Both dilatancy and kinematic constraint may be introduced into a stress characteristics approach while preserving critical state characterization of sand, using the technique known as the method of associated fields. (Author abstract) 24 refs.

**092603 DENSITY VARIATION IN SPECIMENS SUBJECTED TO CYCLIC AND MONOTONIC LOADS.** Control specimens are tested in the triaxial chamber, frozen under back pressure and confining pressure with the top drainage line open, and then dissected into 96 elements in a cold room. The density of each segment and, consequently, the density distribution of the specimen are determined from the ice content. Homogeneity, i.e., relative density uniformity, is quantified in terms of the standard deviation of all elements about the average relative density determined for the 96 elements. Relative density dispersion with an increase in strain level is shown at three densities, approximately 40, 60, and 70% relative density. Density redistribution as a result of cyclic and monotonic loading is demonstrated and quantified in test specimens of Banded sand. (Edited author abstract) 15 refs.

**092604 ENDOCHRONIC MODEL OF SAND WITH CIRCULAR STRESS PATH.** The endochronic constitutive equations developed previously by the writers for the description of sand behavior in true triaxial tests are applied to predict the behavior of Ottawa sand with a circular stress path in the deviatoric stress plane. Predictions by other investigators on the set of data obtained from this stress path are generally poor, and do not even show a qualitative agreement between theories and experiment. It is shown here that the endochronic constitutive equations do lead to reasonable results for this stress path. (Author abstract) 4 refs.

Wu, Han C. (Univ of Iowa, Iowa City, IA, USA); Aboutorabi, M.R. *J Geotech Eng* v 114 n 1 Jan 1988 p 93-103.

**092605 MODULUS AND DAMPING DUE TO UNIFORM AND VARIABLE CYCLIC LOADING.** Laboratory tests are run on five different cohesionless soils to determine their modulus and damping characteristics. Torsional simple shear and resonant column tests are performed by the same test apparatus in order to compare results. Results indicate that the tests are interchangeable as long as there isn't a significant cycles effect. Number of loading cycles generally increases modulus in sands and decreases modulus in silts. Damping decreases with number of loading cycles for both silts and sands. Threshold strain levels are also studied with agreement between predicted and measured results. Ramberg-Osgood parameters, taken with uniform cyclic tests, are applied to irregular loading tests along with the results. (Author abstract) 14 Refs.

## Mixing

**092606 EFFECT OF LOW ELECTROLYTE CONCENTRATION ON HYDRAULIC CONDUCTIVITY OF SODIUM/CALCIUM-MONTMORILLONITE-SAND SYSTEM.** The effect of electrolyte concentration in the percolating solution on hydraulic conductivity (HC) of Na/Ca-montmorillonite-sand mixtures at exchangeable sodium percentage (ESP) 5, 10, and 20 was studied. The HC was decreased following a decrease in electrolyte concentration. The HC of the system at sodium adsorption ratio (SAR) 10 dropped to a very low value ( $4.2 \times 10^{-10} \text{ m s}^{-1}$ ) and no clay was observed in the leachate, when the  $10 \text{ mol}_c \text{ m}^{-3}$  solution was replaced with solutions of lower concentration prior to introducing distilled water. At SAR 5, an increase in HC was obtained when  $1 \text{ mol}_c \text{ m}^{-3}$  solution was replaced with distilled water. This increase was due to clay dispersion and movement out of the system because swelling is limited at SAR 5. (Edited author abstract) 11 refs.

## Moisture

**092607 COMPUTATIONAL MODEL FOR SATURATED SAND SUBJECTED TO CYCLIC LOADING.** The paper presents an analytical model for calculating permanent strains and accumulated pore water pressure due to cyclic loading of saturated sand. The proposed formulation is based on concepts analogous to viscoelasticity to predict strains and pore pressures at the end of one or more cycles of loading without an explicit description of the hysteretic sand behavior within each cycle. Attention is focused on developing general expressions which also partly account for soil anisotropy and the effect of principal stress rotation. The model parameters are derived empirically from the results of drained or undrained static and cyclic triaxial and simple shear tests. The proposed constitutive equations are incremental, in terms of effective stresses, so that they may be applied to predict permanent strains and accumulated pore water pressure under various drainage and boundary conditions.

## Moisture Determination

**092608 INFLUENCE OF WATER CONTENT ON COMPRESSIVE STRENGTH OF FROZEN SANDS.** The authors propose a new experimental equation concerning the compressive strength of frozen sands. This equation and its derivative form define the equi-dry specific gravity lines and the equi-degree of saturation lines. These lines are presented in graphical forms and it is understood that: 1) if the degree of saturation is constant, the compressive strength decreases as the water content increases; 2) the water content at which the maximum compressive strength occurs can be quantitatively determined using the dry specific gravity in the densest state. **092610 ELASTO-PLASTIC CONSTITUTIVE MODEL FOR SAND IN LOW AND HIGH PRESSURE.** An elasto-plastic constitutive model was established in order to describe the stress-strain behavior of normally and over-consolidated sand for static loading in a wide stress region. The fundamental concept herein is based on the assumption that sand can be regarded as an isotropic material. The proposed model which involves eight parameters consists of two set of the yield, plastic potential and hardening functions. These functions are expressed based on a few basic assumptions and experimental evidences obtained from the multi-step stress path tests under 0.1 MPa-10 MPa confining pressure. This model can give good qualitative prediction of shear and volumetric strains for triaxial compression tests with various stress paths on normally and over-consolidated sand in a wide stress region. **092611 MEASUREMENT OF SHEAR WAVE VELOCITIES IN DILUVIAL GRAVEL SAMPLES UNDER TRIAXIAL CONDITIONS.** A method of measuring the shear wave velocity in a triaxial test specimen (300 mm in diameter, 600 mm in height) has been proposed. The validity of the measurement method and the characteristics of the detected waves were confirmed by conducting preliminary tests on a steel cylinder and Toyoura sand specimens. By applying this method, the velocities of the shear waves propagating in the 'undisturbed' samples which were obtained from diluvial gravel deposits by means of an in-situ freezing method were measured under various confining pressures. The results of these measurements indicated that the effect of confining pressure on shear wave velocity was more significant for diluvial gravel samples than for clean sand, and that the shear wave velocities in reconstituted gravel specimens at in-situ overburden pressure were 20 to 30 percent below those in diluvial gravel samples. The shear moduli at a strain amplitude of  $10^{-3}$  in cyclic triaxial tests were about 5

percent less than those determined from measurement of shear wave velocities. It was concluded that the disturbance of the diluvial gravel specimens at in-situ overburden pressure were 20 to 30 percent below those in diluvial gravel samples was very slight during the entire sampling procedure. ## Processing

**092612 SAND PROCESSING, PRODUCT OPTIMIZATION AND WASTE TREATMENT - PART 1. PREPARATION AND SCREENING.** Any sand preparation process begins by physically screening a feed to remove oversize. At this stage in a wet process the desire to reduce the slit content, defined as  $-75\mu\text{m}$ , must also be considered. Feed preparation should aim to scrub off or dilute adhered clay and slit particles from the sand and to break down claybound agglomerates which might otherwise occur often as small balls with the sand or coarse aggregate. The article covers washing, scrubbing and various types of screening operations.

**092613 MODERN GRAVEL AND SAND PROCESSING IN THE NORTHERN UPPER RHINE REGION IN THE KARLSRUHE-MANNHEIM AREA.** The shortage of sand and gravel resources in some conurbations of the Federal Republic of Germany caused by the depletion of the existing deposits, but above all by administrative measures, has compelled the quarry companies to better utilize the deposits presently still available. Thus, in many places, sands and gravel which are strongly contaminated or not corresponding to the standards have to be washed and sized. Producing a premium-quality gravel sand nowadays requires great effort with regard to preparation processing technique. As high additional costs are unacceptable for bulk products such as sand and gravel, modern processing plants must primarily be oriented toward minimization of maintenance, repair and, particularly, energy costs. Besides high-performance component units, this requires above all an optimal design of the entire process. The new sand and gravel processing plant of the Pfander company at Russheim is used as an example of such a production plant oriented toward future demands. **092614 SAND PROCESSING, PRODUCT OPTIMIZATION AND WASTE TREATMENT: PART 5. REMOVAL OF DELETERIOUS MATERIALS AND WASTE TREATMENT.** The presence of lignite (brown coal) in concrete produces staining on a finished surface and leaves behind small cavities as the lignite is weathered out. Lignite occurs in natural sands in a variety of forms from disseminated specks to regular very thin beds and in some cases large fragments of partially fossilized wood. There are several methods of effecting its removal, all relying on the same principle, namely that lignite is intrinsically less dense than sand. Four methods of lignite removal are described, the first two being applicable to gravel, the third and fourth to sand. 12 refs.

## Research

**092615 BASIC RESEARCH ON CUTTING FORCES IN SATURATED SAND.** A theory for the cutting of sand under water has been developed. During the process of cutting saturated sand, the deformation rate

is very important because of the effect of dilatancy. Decreasing pore-water pressure due to dilatancy increases the effective stress. These higher effective stresses result in large cutting forces at high deformation rates. The pore-water pressure changes during the cutting process are calculated, and, subsequently, a prediction is given of the cutting forces. Calculated pore-water pressures and cutting forces are compared with the results of full-scale tests. (Author abstract) 12 refs.

**092616 EXPERIENCE WITH MEASUREMENT OF HORIZONTAL GEOSTATIC STRESS IN SAND DURING CONE PENETRATION TEST PROFILING.** The incorporation of an additional transducer to cone penetrometers has recently been proposed at the University of California at Berkeley. The additional transducer is used to measure the horizontal stress on the friction sleeve, this stress being related to the horizontal geostatic stress of the soil; this type of cone is referred to as a horizontal stress cone (HSC) although it also incorporates a piezometric transducer. The paper derives an algorithm for determination of horizontal geostatic stress from measurements made with an HSC in sand. Some mathematical aspects of the algorithm and how these aspects constrain cone data evaluation are discussed. (Edited author abstract) 20 refs.

**092617 CALIBRATION CHAMBER TESTS OF A CONE PENETROMETER IN SAND.** The results of a series of tests using a cone penetrometer in sand in a large calibration chamber are reported. Sand at three different densities and a range of stress states was studied. The principal finding from the tests is that cone resistance in sand depends primarily on the horizontal stress and the angle of friction but is relatively unaffected by the vertical stress. A relationship between  $q_c$ ,  $\sigma'_h$  and  $\phi'_{1/2}$  is proposed and compared with previous work in calibration chambers. (Author abstract) 5 refs.

**092618 DRAINED PRINCIPAL STRESS ROTATION IN SATURATED SAND.** An investigation into the effects of drained principal stress rotation on the behavior of a saturated medium-loose sand is described. Using a hollow cylinder apparatus the principal stress directions were rotated both at a constant shear stress and under an increasing shear stress during drained monotonic loading to failure. The experimental results are presented. The findings are used to support the notion that a bounding surface, defined by tests with fixed principal stress orientations, can be used to make a qualitative prediction of drained and undrained behavior during monotonic loading to failure which includes rotation of principal stress directions. The bounding surface conveys the importance of both anisotropy in determining strength and the direction of principal stress rotation in determining the magnitude of volumetric strains or pore pressures which develop. **092619 PORE PRESSURE AND EFFECTIVE STRESS IN A HIGHLY SATURATED SAND BED UNDER WATER PRESSURE VARIATION ON ITS SURFACE.** The behavior of pore pressure and effective stress in a highly saturated sand bed under variations in the water pressure on its surface were investigated to determine the mechanism of the collapse of hydraulic structures during flooding or when attacked by storm waves. The vertical, one-dimensional model was used as a basic model to clarify the effect of water pressure variation on only to the vertical direction. The theoretical results show that a sand bed under variations of water pressure is weakened by an increase in excess pore pressure and that under certain conditions the sand bed will liquefy. Although many factors related to water pressure variation and property of the material determine this phenomenon, the most important factor seems to be the small amount of air present in the sand bed. The theoretical results reported are verified by experiments. (Author abstract) 14 refs.

**Testing** See Also SOILS—Reinforcement; SOILS—Strain.

**092620 EXPERIMENTAL OBSERVATIONS OF ANISOTROPY IN SOME STRESS CONTROLLED TESTS ON DRY SAND.** Samples of dry Leighton Buzzard sand have been prepared by pluviation and tested in a true triaxial apparatus and a directional shear cell in order to investigate the response of the sand to series of deviatoric stress probes. True triaxial tests (without rotations of principal axes) showed that dense sand had some significant initial anisotropy as a result of the preparation by pluviation, whereas medium dense sand had negligible initial anisotropy. Sets of probes on samples of medium dense sand with identical histories were used to reveal the link between history and location and size of the current yield locus in both the true triaxial apparatus and the directional shear cell. **092622 CONE PENETRATION TEST IN SANDS: PART II, GENERAL INFERENCE OF STATE.** The state parameter concept provides a new method of characterizing sand behavior, but the utility of the concept relies on the ability to measure the state parameter in situ. In this paper the state parameter approach is applied to data from calibration chamber tests on several sands. It is shown that this approach leads to a common relationship for all the data that includes the effects of material type, quantified by the slope of the steady state line. The state parameter for a sand can therefore be determined in situ with a reasonable precision using a general framework of interpretation which applies to all uncemented sands. **092623 CROSS-HOLE SEISMIC TESTING OF SAND FILL.** In a recent project, the original specification for the soil was for a uniformly graded medium sand, with

particle size of 0.2mm to 0.6mm, and a maximum moisture content of 7 per cent. Sand of this specification is not readily available. Following discussions with the client, it was agreed that a trial embankment should be constructed using selected locally available material, and tested to determine the compressive wave velocity and the bearing capacity under conditions as near as possible to those which would be obtained when the sand was placed on the structure concerned. This paper describes the procedures used during the testing, and comments on the significance of the results.

**092624 POTENTIAL SYSTEMATIC ERROR IN LABORATORY TESTING OF VERY LOOSE SANDS.** There is a potential error in the determination of specimen void ratio in triaxial tests on very loose sands. This error can be attributed to densification during final saturation. The result can be an error in the determination of the location of the steady state flow line in void ratio - stress space. Stress levels on the steady state flow line at a given void ratio may be in error by two orders of magnitude. If carried through to the analysis of susceptibility to liquefaction, this potential error could be extremely unconservative. Test results are presented that illustrate this potential source of error. A laboratory procedure is proposed that provides a simple calculation of final specimen void ratio and is potentially more accurate than presently used procedures. (Author abstract) 11 refs.

**092625 STRESS PATH AND PERMANENT DEFORMATIONS IN SAND SUBJECTED TO REPEATED LOAD.** Presented is a study of the effect of stress path on the development of permanent deformations in sand. Using a pneumatic servo-controlled triaxial system, the confining pressure was varied simultaneously with the axial load. Six different straight line stress paths were investigated; three under compression and three under extension conditions. Dry Ottawa sand was subjected to 100,000 sinusoidal loading cycles at a frequency of 1 Hz. Several loading intensities were used in each stress path. A linear relationship was observed between the permanent axial strain and the logarithm of the number of loading cycles, for constant repeated stress magnitude and constant stress path. Furthermore, based on the results presented here, one can utilize the conventional constant confining pressure triaxial tests to estimate the effect of stress path. Consequently, the results of the conventional tests can be generalized. (Edited author abstract) 14 refs.

**092626 STABILIZATION OF LIQUEFIABLE SAMPLES DURING TRANSPORT.** This technical note presents a new method to transport liquefiable soils from the investigation site to the laboratory. The development of this method resulted from research on liquefiable soils from the Imperial Valley, CA. This method is based upon the application of a slight vacuum on the pore water of the soil. The vacuum decreases the pore pressure, and therefore increases the effective confining stress. Sample recovery and integrity were compared with experiences of others. Comparisons were made in the sample quality after extrusion and sample preparation, as well as the variability of the test result. This method proved to be an improvement over previous techniques. (Author abstract) 6 refs.

**092627 CONE PENETRATION TEST CALIBRATION FOR ERKSACK (BEAUFORT SEA) SAND.** This paper describes a series of calibration chamber tests

carried out on a sand dredged from the Beaufort Sea for construction of artificial islands. This Erksak sand is a uniformly graded, subrounded medium-grained sand with a fines content of 3-6%. The testing chamber described is 1.4 m in diameter, and allows independent control of vertical, horizontal, and back pressures on the sand sample. The chamber test data are presented and confirm that the Erksak sand fits the general trends observed for other sands very well. A method is also described that allows the interpretation to be consistent, even in the event that nonuniform void ratios occur in the samples. Measurements of horizontal stress behind the cone tip, which is a new development in cone penetrometer testing, are also presented. (Edited author abstract) 14 refs.

Been, K. (Golder Associates, Calgary, Alberta, Can); Lingnau, B.E.; Crooks, J.H.A.; Leach, B. *Can Geotech J* v 24 n 4 Nov 1987 p 601-610.

**092628 BEHAVIOR OF SAND PARTICLES IN SAND-STEEL FRICTION.** This paper describes a method for observing the particle behavior near the interface in sand-steel friction tests. A friction testing apparatus was modified to allow the observation of sand particles. Close-up photographs were taken of the sand particles at specified timing in sand-steel friction tests. The change in particle coordinates gives the displacement of particles during the friction test. The sand-steel interface showed a small amount of sliding before the peak in the frictional resistance. The sand on a smooth steel surface slid without large shear deformation. The sand particles on a rough steel surface rolled as well as slipped along the interface. These movements caused the formation of a shear zone within the sand along a rough interface. (Edited author abstract) 16 refs.

**092630 INTERPRETATION OF FLAT PLATE DILATOMETER TESTS IN SANDS IN TERMS OF THE STATE PARAMETER.** This paper assesses the key parameters which govern the expansion stage of a flat plate dilatometer (DMT) test in cohesionless material in order to develop relevant correlations with respect to the compressibility of sands. Laboratory tests in a small calibration chamber were conducted to obtain a response from the DMT during expansion in undisturbed Ottawa sand under a given stress field. The deformation characteristics inferred from the DMT data compared well with those obtained from triaxial tests. The results from the DMT are best interpreted in terms of the state parameter which combines the influence of void ratio and stress level with reference to the steady state line of the soil. A framework based on the normalized state parameter for the interpretation of DMT test profiles in most sands is proposed. (Edited author abstract) 12 refs.

**092632 SIMPLE SHEAR TESTING ON SAND IN A TORSIONAL SHEAR APPARATUS.** A method for simple shear simulation using a hollow cylindrical specimen is described. Drained tests at controlled axial stresses were performed automatically by means of a servo-system consisting of a micro-computer and a pneumatic-controlling system. For undrained tests on saturated specimens the simple shear simulation was achieved only by a mechanical means. The torsional simple shear behavior of Toyoura sand is described. It was found that the strength and deformation properties of Toyoura sand at relatively large strains in torsional simple shear are very similar to those by the plane strain compression test in which the directions of principal stresses with respect to the deposition direction and the value of  $\sigma_3'$  are similar to those at failure in the torsional simple shear test. ## Thermal Conductivity

**092634 MEASUREMENTS OF THE EFFECTIVE THERMAL CONDUCTIVITY OF DISPERSED MATERIALS.** The transient hot wire method was used to measure the effective thermal conductivity,  $\lambda_e$ , of several sands under various conditions. The method has been found to be well suited and appears advantageous for its quickness. The effective thermal conductivity of dispersed materials was found to depend strongly on porosity, water content, and thermal conductivity of the moistening liquid; and to depend weakly on grain size and grain geometry. There is an effect of temperature on  $\lambda_e$  for temperatures between 20 and 70°C which seems to be due to the temperature dependence on the thermal conductivity of the gas or liquid involved. (Author abstract) 14 refs.

## Vibrations

**092636 LEVEL GROUND SOIL-LIQUEFACTION ANALYSIS USING IN SITU PROPERTIES: I.** A fundamental approach utilizing the electrical properties of soils to characterize their grain (particle shape) and aggregate (porosity and fabric anisotropy) characteristics is presented. Correlations between mechanical properties relevant to the analysis of soil liquefaction and electrical indices defining the structure of a soil are given, and the influence of fabric anisotropy on mechanical behavior of soils is demonstrated. The nondestructive nature of the proposed method provides a means to predict in situ properties and thus overcome the difficulty of retrieving undisturbed samples. (Edited author abstract) 30 refs.

Arulanandan, Kandiah (Univ of California, Davis, CA, USA); Muralletharan, Kanthasamy K. *J Geotech Eng* v 114 n 7 Jul 1988 p 753-770.

**092637 LEVEL GROUND SOIL-LIQUEFACTION ANALYSIS USING IN SITU PROPERTIES: II.** A method is presented for level ground soil-liquefaction analysis, which is treated as a boundary value problem. This method uses a semiempirical, one-dimensional, elastoplastic constitutive model and finite difference method to solve the governing differential equation for the prediction of pore pressure generation, dissipation, and settlement characteristics during and after dynamic excitation. A compressibility function incorporating effects at low effective stresses is included in this method, which is verified by centrifuge model tests. This procedure utilizes input properties representative of field conditions determined by a nondestructive electrical method. The proposed method for analyzing the generation and redistribution of pore pressure, therefore, provides a means for predicting liquefaction of level ground sites - a boundary value problem - based on the results of in situ testing. (Edited author abstract) 30 refs.

**092638 CENTRIFUGE LIQUEFACTION TESTS IN A LAMINAR BOX.** The difficulties associated with instrumenting earthquake sites in order to record pore pressure changes in a future event led to the use of scaled model tests performed in a centrifuge. Both dry and saturated sands were employed, contained in a box constructed of aluminium laminae designed to move freely on each other. This would result in shearing distortions developing in the soil unimpeded by the container. Accelerometers, displacement transducers and pore pressure sensors were attached to the box and embedded in the soil at various elevations so as to record the response of the soil to an earthquake-like excitation supplied to the base of the container. A special apparatus was constructed to imitate earthquake motion. In some tests on saturated sand, the soil profile was liquefied. Study results are discussed. (Edited author abstract). 20 Refs.

**092639 DYNAMIC MODULI AND DAMPING RATIOS FOR CEMENTED SANDS AT LOW STRAINS.** This paper advances the present understanding of the beneficial effects of cementation of sands on their dynamic behavior at low strain amplitudes. The influence of important parameters such as cement content, effective confining pressure, density, and curing period is discussed in detail on the basis of extensive resonant column test results. A newly proposed relationship for maximum dynamic shear modulus is compared with reported relationships. Empirical relations for maximum dynamic Young's modulus, dynamic shear damping, and dynamic longitudinal damping are developed for the first time. All the relations developed are nondimensional and adaptable to any system of units. Correlations between dynamic

moduli and static strength from triaxial (drained) tests are developed for an effective confining pressure equal to 49 kPa. (Author abstract). 21 Refs.

**092640 COHESIONLESS SOIL BEHAVIOR UNDER RANDOM EXCITATION CONDITIONS.** A testing program was undertaken in which dry sand at different confining pressures was tested in a resonant column device using random torsional excitation in addition to conventional sinusoidal loading. The concept of the root-mean-square (rms) strain, as well as the use of the extreme value theory to determine the peak shearing strain under random excitation, is presented. The transfer function method was used for the first time in soil testing. Evaluation of the dynamic soil properties for sinusoidal vibration followed conventional procedures. During random loading, the damping values are higher and the shear moduli lower than the values obtained from sinusoidal loading at the same rms strain. Formulas were developed to correct the damping and shear moduli obtained from routine sinusoidal testing. (Edited author abstract). 28 Refs.

**092644 SAND DIEGO SAND AND GRAVEL OPERATION MOVES MOUNTAINS.** In keeping with its portable company status, Dave Martin Supplies does not own a permanent crushing facility. A limited amount of crushing is performed for them by a local company. The company owns Read RD-90 and RD-150 portable screening units. They are moved around the company's main yard, located northeast of San Diego, or transported to specific job sites for use in a variety of projects. One such project was the removal of 500,000 st of material from the side of a local hill to make a place for a 20-ft-high by 200-ft-diameter water tank.

Kuhar, Mark S. *Pit Quarry* v 81 n 2 Aug 1988 p 117-119.

## Construction

**092645 CONSTRUCTION OF A NEW GRAVEL PLANT ON THE NORTHERN PERIMETER OF THE HARZ MOUNTAINS.** In 1985, Messrs. Oker, Kies and Splitt GmbH & Co, Kieswerk KG, Schladen, West Germany placed an order for a new gravel preparation plant stipulating that it should be designed to meet the changed demands of the building trade and be operated with a minimum of manpower. The task of the new plant was to prepare graywacke gravel with a grain size of 0-150 mm won by dredging. The order specified a 0.09/0.25 fine sand fraction of 12-20% in 0/2 sand. Since the fine sand fraction was not high anyway, wastage during the preparation process had to be avoided as much as possible. However, in view of the high power requirements, a pump-cyclone system for desilting was not allowed. In German and English.

Wittwer, G. *Aufbereit Tech* v 28 n 6 Jun 1987 p 331-335.

## England

**092646 RAIL-FED COATING DEPOT UPRATED BARDON HILL'S LONDON TERMINAL FULLY OPERATIONAL.** A little over a year ago the Bardon Hill Group opened their new rail off-loading and aggregate storage facility at West Drayton in Middlesex. Phase two of the development of Bardon's London terminal, which included the modernization of on-site coating plants, began afterwards and is now reaching completion. The result is a twin-plant operation with a combined capacity of some 700 tonnes/h.

**092647 KOMPAKTANLAGE ZUR TROCKENAUFBEREITUNG VON FEINSAND MIT MOGENSEN-SIZERN UNTER NUTZUNG VON DEPONIEGAS.** [Compact Unit for Dry Processing of Fine Sand with Mogensen Sizers Using Gas from Disposal Sites]. Dry quartz sands yield significantly higher profits than wet sands; they can also be sized at a higher separation efficiency. This is why dry sizing is used in a new unit at a quartz works near Stade in northern Germany for producing five commercial grain sizes. In order to reduce the high energy costs for drying the feed material, energy from waste (gas from disposal sites) obtained from a rubbish tip located near the plant is used. The unit is laid out for 20 tph dry sand; it operates free of clogging, is enclosed to seal in dust and is of particularly compact design. By placing three Mogensen sizers above the block of five silos, no further conveyors are required for filling them. The compact design and the low weight of the screening station permit an economical supporting structure. The utilization of cheap gas from disposal sites and the intelligent, but simple plant concept lead to exceedingly economical production of commercial products. (Edited author abstract) In German and English.

## Illinois

**092650 CHICAGO QUARRIES ADAPT TO CHANGING MARKETS.** Among production leaders for many years, two Chicago area plants, Vulcan Materials Company's McCook Quarry and Material Service Corporation's Thornton Quarry, have continued high output and profitable operations as they adapt to changing market needs. Each plant recently installed a specialized production facility to increase output of high-demand products. Vulcan's McCook installed a processing plant for shore protection rip-rap, while Material Service put in a crushing/screening auxiliary facility for increased production of - 1 in material.

Anon. *Quarry Manage* v 15 n 2 Feb 1988 p 35-36.

## Modernization

**092651 RETROFIT PROGRAM REVITALIZES OLDER SAND & GRAVEL PLANT.** The plant of Elam Sand & Gravel, Inc., Victor, NY, has been revamped to produce 300 t/h of what is claimed to be the cleanest sand product in the state. A major capital investment in new processing equipment, coupled with an accelerated maintenance program, have expanded production capabilities by 8 products. The process of transforming the 1960-vintage plant into a high-efficiency facility capable of meeting current sand specifications required two months, and more than \$30,000 in parts alone, including new pulleys, rollers, shafts, bearings, and conveyor belts, according to Leo Spezio. In addition to sand processing equipment, new purchases included 3 Caterpillar front end loaders and five new Mack tri-axle trucks.

Michard, Don. *Pit Quarry* v 80 n 8 Feb 1988 p 46-48.

**092652 J.L. SHIELY CO. UPDATES VETERAN SAND/GRAVEL PLANT.** In a program to optimize the productivity of its 900-acre Nelson Plant in the Twin Cities metropolitan area, management of J.L. Shiely Company has been conducting a long term program of processing system improvement and site reclamation. Conversion to urethane screening media and modern crushers has raised production while extending life of the deposit. Most of the production is barged to the St. Paul/Minneapolis downtown area.

## Ohio See Also SCREENS AND SIEVES—Plastics Applications.

**092653 DEWATERING A SAND-RICH GRAVEL DEPOSIT.** American Aggregates installed a bucket wheel at its sand-rich Newark, Ohio, facility for efficient sand dewatering. The wheel rotates one revolution every 50 seconds, handling 200 tons of sand per hour. As a result, this dredging operation has cut maintenance costs and increased production while producing a drier product.

Adams, Bruce. *Pit Quarry* v 80 n 2 Aug 1987 p 28-29.

## Productivity See Also EARTHMOVING MACHINERY—Mechanical Drive.

**092654 GETTING OUT OF A STICKY SITUATION.** A Michigan sand and gravel producer changed processing methods and significantly decreased clay problems. The new plant, incorporating a portable Universal ImpactMaster II, has eliminated the need to remove clay balls and, in this application, can out-produce both jaw crushers, according to Miller. After dredging material, wheel loads feed the crushing/screening plant. A hopper with underlying feeder belt is charged using one or two of the firm's Hough loaders. Material is conveyed to the Universal ImpactMaster II, equipped with a double-deck Allis-Chalmers vibrating screen. Top deck overs are crushed; bottom deck overs can either be crushed or stockpiled; bottom deck throughs can be entirely stockpiled or partially mixed with coarser material from the bottom deck.

## Water Recycling

**092655 KLAERUNG UND FEINSCHLAMMBEHANDLUNG IN SAND- UND KIESAUFBEREITUNGSANLAGEN.** [Clarification and Treatment of Fine Slurries in Sand and Gravel Preparation]. Washery and circuit water from sand and gravel treatment plants may be clarified successfully with polymeric flocculants. The clarified water can be reused in the washery circuit or discharged without problems. There are well-proven clarifying systems available with integrated dissolving and dosing equipment for polymeric synthetic flocculants. If required, the sedimentated and thickened slurries can be dewatered at low cost by application of polymeric flocculants with decanter centrifuges, sieve belt presses or chamber filter presses. (Edited author abstract) In German and English.

Reuter, J.M. *Aufbereit Tech* v 28 n 3 Mar 1987 p 148-155.

**092656 DEWATERING OF SLUDGE IN GRAVEL WORKS WITH BELT FILTER PRESSES AND CHAMBER FILTER PRESSES USING RECYCLING OF WASH WATER.** For wet processing, the recycling of wash water is necessary with respect to political aspects and thus has an economical purpose. The economy of this process is explained by using an example from gravel processing. The contaminated wash water is cleaned in a clarification reactor and re-used as wash water in the gravel preparation plant. The sludge which is formed can be dewatered with belt filter presses and chamber filter presses. The process scheme of the complete unit, the clarification reactor, the belt filter presses and the chamber filter presses are described. Operating results and technical data are listed. (Author abstract)

## SAND, FOUNDRY

**092657 POLYCYCLISCHE AROMATISCHE KOHLENWASSERSTOFFE IM FORMSAND.** [Polycyclic Aromatic Hydrocarbons in Molding Sands]. Polycyclic aromatic hydrocarbons as a materials group of organic compounds which occur both in nature and are produced during incomplete combustion of organic materials. Some of these materials are carcinogenic. This article deals with the hazards generated by these hydrocarbons present in foundry sands. Results of examinations of samples of used sands from 10 foundries are presented and evaluated. In German. 26 refs.

Kleinheyer, Ulrich (VDG, Duesseldorf, West Ger); Schmittner, Hartwig; Staufenbiel, Richard; Wolf, Dieter; Zindler, Guenter. *Giesserei* v 74 n 21 Oct 12 1987 p 640-643.

**092658 NEW CONCEPTS OF GREEN SAND TECHNOLOGY - PART II.** As Part I of this two-part article emphasized, molding sand tolerances have become tighter since use of compaction by vibration has declined. Significant changes in sand properties and molding problems are caused by increase core sand inflow, condensate accumulation, decreased temperature moisture, faster sand recycling, reduced preparation times, and higher compaction. This concluding article addressed those problems, assesses production risks, and advises about better foundry practice. (Author abstract)

Boenisch, Dietmar (Univ Aachen, West Ger); Ruhland, Norbert. *Foundry Manage Technol* v 116 n 3 Mar 1988 5p between p 38 and 49.

**092659 SELF MOULDING CHEMICALLY BONDED SANDS.** Since most jobbing foundries have had to tackle more cost effective production and higher demands for quality against a reduced demand for castings and selective skills shortages, effort has been put into semi-mechanised systems. In mouldmaking the parallel developments in chemically bonded sands have continued to achieve the foundryman's goal supplying the right quality at the right price. The implementation of machines for moulding chemically bonded sands has helped Hawthorth Castings achieve consistent quality competitively by the elimination of much core setting and reduced fettling.

Anon. *Foundry Trade J* v 162 n 3363 Feb 11 1988 p 86, 88.

**092660 STATISTICAL EVALUATION OF THE PROPERTIES OF MOLDING SANDS IN CHENGDU AND SYNTHETIC ANALYSIS OF THE PROPERTIES AND THE CASTING QUALITIES.** The author analyzed green molding sands from 44 different iron foundry shops in Chengdu. Ten properties of the molding sands were tested. The test data was processed by computer. In this area of Chengdu two thirds of the casting defects are caused by blowholes, sand inclusions and crushes. The clay contents are too high and the moisture contents are excessive. The paper presents reference targets for suitable properties of molding sands. (Edited author abstract) 3 refs. In Chinese.

Jiang, Yixiang (Sichuan Inst of Technology, China). *Zhuzao* n 12 Dec 1987 p 12-16.

**092661 RAPID MONITORING OF ACTIVE CLAY CONSTITUENT CONCENTRATIONS.** In the USSR molding problems are responsible for 70% of reject castings. The flaws produced by defective molding sand arise from the amount of clay constituent in the sand, the degree of wetting (the bentonite/water ratio) and the quality of the clay constituent. A rapid monitoring test has been developed on the basis of the release of basic exchange ions ( $K^+$ ,  $Na^+$ ,  $Ca^{2+}$ ,  $Mg^{2+}$ ) by interaction with water which characterizes the binding capacity. The same test can be used to determine the degree of bentonite activation obtained by adding soda ash. 2 refs.

Lysochenko, V.V.; Tkachenko, Yu.K.; Krasil'nikov, Yu.K.; Lesnov, V.N. *Sov Cast Technol* n 8 1987 p 12-14.

**092662 ENHANCING THE FLOWABILITY OF CLAY SUSPENSIONS.** The strength of baked molds can be enhanced by introducing the clay in the form of a suspension (slip) prepared from lump material. The authors investigated the possibility of enhancing the flowability of low-grade clay slips by adding fluidizers such as sulfite yeast lye (SYL), sodium hexametaphosphate (SHMP) or sodium bentonite. The use of high-flowability slip eliminates the fouling of distribution pipelines and gives a 30-40% increase in permeability, a 30-50% increase in sand strength, and a 10-15% reduction in water content. SYL, SHMP, and bentonite can be used in this way to adjust molding sand properties over a wide range.

Kuz'min, N.N.; Komissarov, V.A.; Rodin, V.A. *Sov Cast Technol* n 7 1987 p 20-22.

**092663 PHENOL DESTRUCTION IN FOUNDRY WASTEWATER.** Phenols and phenolic compounds are toxic materials generated in foundries by some sand binders and by the combustion of coke. Phenolic compounds appear in foundry wastewater streams in varying concentrations. Local and state limitations on the discharge of phenolics have been in effect for a number of years. However, stricter regulations for the foundry industry were promulgated by the U.S. Environmental Protection Agency (EPA) in 1985. Full compliance with these regulations is mandated by Oct 31, 1988. This examination of current technology for the destruction of phenolics in foundry wastewater streams includes a presentation of new technology using chlorine dioxide to destroy phenolic compounds. Biological digesters, potassium permanganate and hydrogen peroxide are also discussed. 4 refs.

## Additives

**092664 STRUCTURE AND PROPERTIES OF ANTI-BURN-ON DRESSING FOR COLD-SETTING RESIN-BONDED SANDS.** Tests have been carried out on an anti-burn-on dressing containing 65 wt.% zircon flour and 35 wt.% resin KO-0168 for large molds and cores made from cold setting resin-bonded sands. This mixture has a low resistance to sedimentation and the dressings are liable to craze when heated to high temperatures. Inorganic stabilizers (aerosils with different specific surface areas) were examined with a view to stabilizing the dressing mixture and strengthening the coatings at 900-1500°C. Statistical analysis confirmed a reduction in burn-on and surface flaws when using dressings with superior properties.

Gulyaeva, T.B.; Velikanov, G.F.; Brechko, A.A. *Sov Cast Technol* n 1 1987 p 19-21.

**092665 INVESTIGATION ON THE PREGELATINIZED STARCH ADDITIVES FOR GREEN MOLDING SAND.** Pregelatinized starch (a starch) additive is used in foundries of western countries but less in China. Effects of several pregelatinized starch products on properties of moulding materials were studied. The results show that pregelatinized starch improves the stripping property, anti-friability, anti-erosion and anti-scabbing properties of molding sand and improves the quality of green sand castings. (Edited author abstract) 5 refs. In Chinese.

Yu, Zhenzong (Qinghua Univ, China); Zheng, Dianjun; Wang, Zhigang; Wang, Yafeng. *Zhuzao* n 1 1988 p 7-12.

**092666 ENHANCING THE PLIANCY OF RESIN-BONDED SANDS.** Pliancy tests have been carried out in the Kupyansk foundry on sands containing oxidizing and mineral additives. Stress analyses on the castings showed that the residual stress levels are lowered by 10-15% in the presence of 0.2% of oxidizer and by 30-35% in the presence of 1% expanded vermiculite. Hydrated silicates are preferable in wet-mixed resin-bonded sands and oxidizers in the resin-coated sand type of mixture. 1 ref.

Sinchugov, A.Yu.; Chernenko, N.G.; Voronin, Yu.F.; Kolotilo, D.M. *Sov Cast Technol* n 8 1987 p 15-17.

**092667 USE OF STARCH PRODUCTS TO COMBAT SCALING.** Various additives can be used in molding sands to combat the formation of scabs and scales. They include starch products made by the heat treatment of starch/albumen suspensions or the extrusion treatment of corn grain wastes. The authors investigated the effects on the tensile strength of molding sands in the water condensation zone of a number of starch products, i.e., krakhmalit, extruded starch reagent and starch products modified by extrusion. The addition of starch products is only effective in molding sands bonded with unactivated bentonite.

Gordeev, G.D.; Kiselev, V.L.; Lysochenko, V.V. *Sov Cast Technol* n 8 1987 p 64-65.

**092668 INFLUENCE OF PHOSPHATES ON PROPERTIES OF SOLUBLE SILICATE AND MOLDING SANDS.** The knock-out properties of silicate-bonded sands are usually improved by lowering the soluble silicate content and adding a variety of organic and inorganic additives, singly or in combinations. The basic sodium salts of phosphoric acid meet the technical requirements. The best among them is sodium triphosphate (STPP). This work compared STPP with trisodium phosphate. 4 refs.

Sychev, I.S.; Vishnyakov, K.I.; Skazhennik, V.A. *Sov Cast Technol* n 7 1987 p 27-30.

## Adhesion

**092669 ELIMINATING THE ADHESION OF LIQUID SELF-SETTING SANDS TO PATTERNS AND PATTERN PLATES.** A study has been made of the composition of expendable parting agents used to prevent liquid self-setting (LSS) sands from sticking on wooden and more particularly metallic equipment. However, these parting agents have failed to suppress sand adhesion to an adequate extent; the useful life of the semi-permanent coating only averages 8-10 cycles. As the coating of semi-permanent parting agent is attacked by the kerosene, the prepared surfaces become rougher; much more LSS sand sticks on and eventually the surface finish of the halfmolds, cores, and castings deteriorates. The problems can be overcome by adopting a novel parting agent (USSR Author's Certificate No. 755408), consisting of 75-85% diesel fuel as the vehicle and 15-25% added paraffin wax. The use of diesel fuel has substantially prolonged the useful life of pattern equipment and eliminated the adhesion of LSS sands to wooden patterns.

Guba, A.I.; Maksimenko, G.U. *Sov Cast Technol* n 3 1986 p 76-77.

**Binders** See Also FOUNDRY PRACTICE—Coremaking; FOUNDRY PRACTICE—Molding; IRON FOUNDRY PRACTICE—Coremaking; STEEL CORROSION—Electrochemical.

**092670 SILICATE-BONDED HOLDING SANDS WITH IMPROVED PROPERTIES.** The analysis of the two-dimensional model sections showed that the optimum proportions, which give the required strength, life and knockout quality ( $W \leq 3$  J) are within the range: soluble silicate 4.5-5%, remainder ferrochromium slag and sodium sulfite. The sodium silicate content must be  $\geq 4.5\%$ , otherwise the sand is lacking in strength, but above 6-8% soluble silicate the knockout quality is impaired. The useful life, denoting the time interval between bringing the sand into contact with the hardener and making the core or mold, must satisfy the requirements for making medium-size and large cores. Beyond this period, the sand becomes less compactable, and more friable, i.e., its useful life has expired. A table compares the compressive strength and friability data on specimens compacted after increasing delays. 3 refs.

Vasin, Yu.P.; Bortnikov, M.M.; Gurlev, V.G.; Kasatkina, V.I. *Sov Cast Technol* n 4 1986 p 19-22.

**092671 COMPOSITION/DENSITY RELATIONSHIP IN SODIUM SILICATE.** The allied sectors that produce ZhS do not supply a product with the density and silicate module values required for castings production. The problem has arisen of organizing the production of sodium silicate in lump or possibly dissolved form (as ZhS) so that foundries can be supplied with ready-made silicate binders. This requires accurate data on the influence of ZhS composition on its density. An additional composition characteristic is the water content W, found by difference from the above characteristics ( $\%W = 100 - \%SiO_2 - \%Na_2O$ ). The total insoluble impurities content (covering Al, Fe, and Ca oxides plus  $SO_3$ ) must be below 0.6% for sodium silicate (according to GOST 13078-81) and can be ignored for the purposes of calculation. The above characteristics are interrelated: given any two, the others can be found and are invariant.

Afanaseva, R.S.; Teplyakov, S.D. *Sov Cast Technol* n 4 1986 p 23-25.

**092672 STRENGTH OF MOLDING SANDS.** Petrographic sections of typical sands were examined in areas of grain-boundary failure and on contact faces, using binocular mineralogical and biological microscopes (POLAM-II and MBI-15U). Examinations in ordinary and polarized light and by the phase-contrast clay-bonded sands with a cohesive strength mechanism. Examinations in ordinary and polarized light and by the phase-contrast procedure failed to reveal any areas devoid of a binder film on the sand grain surfaces. The mode of failure was by direct loss of adhesion or a combination of adhesive and cohesive breakdown in all the molding sands examined. Maximum strength is obviously exhibited by sands in which the adhesion and cohesion forces are equally balanced. If either force predominates, the system loses its equilibrium; its overall strength is reduced and in some cases the sand can collapse spontaneously. Since molding sands constitute dissipative systems, in which the binder structuring process is unstable and progresses in the direction of reduces degrees of freedom for individual elements of the supramolecular structure, the vital factor is the selection of a composition which has near-equilibrium properties over the period required for practical use. 6 refs.

Velikanov, G.F.; Primak, I.N.; Brechko, A.A. *Sov Cast Technol* n 3 1986 p 16-19.

**092673 MODIFIED PHENOL-UREA-FORMALDEHYDE BINDER FOR CORE SANDS.** Hot-box coremaking in foundries has been largely based for some years on resins KF-90, BS-40, and SF-411. The phenol-urea-formaldehyde resin SF-411 is the most economical, since it does not contain expensive furanols. It provides good setting rates and high strength properties in resin-bonded sand specimens (comparable with carbamide-furan resins). The high reactivity of resin SF-411 is explained by the presence of up to 8% free formaldehyde and 25% methylol groups, which participate actively in the resin structuring processes at elevated temperatures. The major drawbacks are the high free phenol content (up to 7%) of the resin and its short shelf life. The Kemerovo Chemical Industry Research Institute has developed a resin grade FML, of higher reactivity and lower toxicity than grade SF-411. 2 refs.

Kozlova, G.I.; Dubikovskaya, L.V.; Kvasha, F.S.; Lamasov, A.A. *Sov Cast Technol* n 3 1986 p 30-31.

**092674 LOW-TOXICITY COLD-SETTING BINDER 'FURITOL-30'.** It was established that Furitol-30 has superior reactivity and binding capacity than the popular binders for CS sands (OF-1, FS-40, etc.). There is no irritant odor. The volatile contents of the air remained below the PDK limits at all points in the sand preparation, molding and coremaking and pouring bays. The surface finish and general strength of the molds and cores remained satisfactory at catalyst contents from 25 to 65% by weight of binder. The coresand is capable of hardening at relatively low temperatures (5 K above the shop temperature). Pilot commercial trials have shown that binder Furitol-30 meets all the technological and industrial health requirements for castings production and

can be used for molding and coremaking in foundries making steel or iron castings of any weight.

Antonov, M.M.; Pechennikova, T.I.; Bekbulatov, I.A.; Vidyakina, L.M.; Skobelina, Yu.P. *Sov Cast Technol* n 3 1986 p 34-35.

**092675 IMPROVING THE KNOCKOUT BEHAVIOR OF SILICATE-BONDED SANDS.** The coresands used in the foundries at the Elektrotvazhmash, LEZ (Elektrosila) and REZ (Riga Electrical Engineering) Works contain up to 8% of soluble silicate, and are difficult to knock out. The easiest way of improving their knockout properties under these foundry conditions is to introduce additives which will aid the disintegration of the cores and molds at the knockout stage. The purpose of the additives is to form refractory multi-component compounds with the soluble silicate, which will melt in this case at temperatures well above the second peak on the curve of knocking-out energy. The labor costs of knocking out and fettling can be halved by using the proposed mixture. The greatest improvement is attained when the cores and faced molds reach the temperature of kaolin phase transformation (1000-1100°C), which is usually the case when the core is surrounded by metal on all sides except for the print. Thus, the most acceptable method at present available to the Elektrotvazhmash, LEZ LPEO Elektrosila and PO REZ foundries for improving the knockout behavior of silicate-bonded sands is to introduce weakening additives, and the most effective of these is kaoline. 2 refs.

**092676 LIQUID SELF-SETTING SANDS BASED ON SULFITE-YEAST LIQUOR.** The mechanism of the setting of LSS sands based on sulfite-yeast liquor and chromic anhydride or sodium persulfate has been analyzed. The entire range of possible variants should be studied, to ascertain the optimum conditions for the formation of strong gels by the treatment of SYL with plentiful and cheap materials with a high oxidizing potential.

Ektova, V.N.; Kozuseva, T.I. *Sov Cast Technol* n 3 1986 p 39-40.

**092677 BINDER FOR MAKING FOUNDRY CORES AND MOLDS FINISHED BY BAKING.** The possibility of using the oil-grease residue from black cotton oil, lacquer grade gasoline and a sicative as a binder mixture has been investigated with a view to enhancing the strength of baked cores and molds, shortening the baking period of the molding sand, replacing raw materials in short supply, and reducing atmospheric pollution. The oil-grease residue from black cotton oil was mixed with white spirit for 20-40 min without heating, and the calculated amount of sicative was added when the mixture became uniform. The residue in question is a mixture of saturated and unsaturated fatty acids in the range  $C_{12}-C_{22}$  and polyphenolic gossypol derivatives (iodine number  $\geq 100$ , and acid number  $\leq 90$  mg KOH per gram of residue). The sicatives used were both technical products, NF-1 or 64b. The binder preparation by the new technology utilizes more plentiful and less costly raw materials. The use of the new binder for molding and coremaking has led to higher strength after a (25%) shorter baking period. The proposed binder contains less volatile materials and is less toxic.

Moshoshina, M.N. *Sov Cast Technol* n 3 1986 p 78.

**092678 GAS-FORMING CAPACITY DURING POURING OF SANDS WITH SYNTHETIC BINDERS.** Hungarian foundries use sands based on synthetic resins. On occasion they encounter gas-produced defects, particularly when using sands of Hungarian origin. The most widely used resins are DORFIX-A and THERMOFIX FFK. The gas formation dynamics in cores can be determined by a described procedure. The article includes some of the results and their bearing on the prevention of defect formation.

Tot, L.; Nandori, D. *Sov Cast Technol* n 12 1986 p 34-37.

**092679 RESEARCH ON A SUSPENSION AGENT OF ALCOHOL BASED COATINGS.** The article describes an inorganic ion exchanged Li-bentonite as the suspension agent for alcohol based coatings. This suspension agent uses an auxiliary agent which can improve the suspension stability over 90% within 8 hours. Compared with organic bentonite, the suspension agent is less expensive and is beneficial in foundry practice. In Chinese.

**092680 STUDY ON  $SO_2$  PROCESS AND ITS APPLICATION.** The  $SO_2$  process, characteristics of resin TTY-1 and properties of  $SO_2$  resin bound sand have been studied. The application of the  $SO_2$  process in the manufacture of cores of submerged pumps is described briefly. (Edited author abstract) In Chinese.

Shen, Yan (Tianjin Inst of Machinery Research & Design, China). *Zhuzao* n 5 May 1987 p 13-15.

**092681 STRENGTH AND KNOCKOUT PROPERTIES OF SILICATE-BONDED SANDS.** Standard methods of investigation were applied to finding the structural characteristics of silica gels prepared by treating an aqueous solution of sodium silicate with carbon dioxide. The structural characteristics were modified by adding strengtheners to the sodium silicate solution. The additives included aliphatic amines and multi-component commercial mixtures of aromatic alcohols and their simple esters. The most effective way of improving the knockout properties of silicate bonded sands is to use additives which simultaneously strengthen the sand before pouring, weaken it after heating, and lower the necessary binder content. 3 refs.

Zhukovskii, S.S.; Ivanov, A.A. *Sov Cast Technol* n 1 1987 p 14-18.

**092682 USE OF MODIFIED SOLUBLE SILICATE BINDERS TO IMPROVE FETTLING-SHOP WORKING CONDITIONS.** Ways of improving the knockout properties of silicate bonded sands and the working conditions in fettling shops can contribute towards higher labor productivity. The authors carried out a planned study of the problem and derived regression models which characterize the influence of production factors on employee performance. Using the modifying additives ( $NH_4$ ) $_2$  $SO_4$  and  $Na_2SO_3$  improves the initial strength properties of silicate-bonded sands and makes them easier to knock out after heating in the poured molds. This reduces the labor costs of knocking out and the dust content of the workplace. 5 refs.

**092683 PREPARATION OF SOLUBLE SILICATE CONTAINING SODIUM TRIPOLYPHOSPHATE.** The addition of sodium tripolyposphate (STPP) to soluble silicates both increases the initial strength of silicate-based molding sands and makes the used sand easier to knock out after heating to high temperatures. The additions can be made either during soluble silicate production, at the autoclave digestion stage, or later. Both methods have been investigated. They give different results arising from the properties of alkaline aqueous STPP solutions at room temperature and during heating to 190°C. 2 refs.

Sychev, I.S.; Skazhennik, V.A. *Sov Cast Technol* n 1 1987 p 63-64.

**092684 INVESTIGATION AND APPLICATION OF ALCOHOL BASED COATINGS FOR CAST IRON AND STEEL IN HIGH PRESSURE MOULDING LINE.** In a high pressure moulding line green sand moulds are used for cast iron and steel. In order to guarantee the surface quality of castings and eliminate defects of the adhering sand, spraying of alcohol based coatings is adopted. The authors have developed three types of alcohol based coatings. Their refractory fillers are

graphite, alumina and zircon. The application of lithium ion exchanged bentonite and an auxiliary agent can produce a suspension stability of over 90% within 8 hours. (Edited author abstract) In Chinese.

Ye, Kongrong (Taiyuan Univ of Technology, China); Wang, Boyin; Xie, Fanqun; Chang, Jinshan. *Zhuzao* n 9 Sep 1987 p 26-30.

**092685 PROPERTY CHANGES IN CLAY-BONDED MOLDING SANDS DURING POURING.** After pouring a mold, the binder (clay, bentonite) in the sand layers immediately outside the casting loses its strength virtually completely. With increasing distance from the casting, the temperature reached by the sand becomes lower and the degree of weakening steadily decreases. It has been established that sand heated to 180-200°C undergoes no significant changes in properties, whereas at 550-620°C the bentonite entirely loses its binding capacity. These temperatures mark the boundaries between three distinct layers of sand in the poured mold: completely degraded, partially weakened, and still retaining the initial strength. If used sand is repeatedly recycled, fresh clay must be added to it in order to restore its strength to the standardized level.

Kartashov, V.T.; Medvedev, Ya.I.; Ivanov, N.Kh. *Sov Cast Technol* n 3 1987 p 35-36.

**092686 PHOSPHATE-BONDED COLD-SETTING SANDS FOR STEEL AND IRON CASTINGS PRODUCTION.** From the point of view of foundry technology requirements, a system must set in air over a short interval of time (1-5 min). This setting rate is ensured by using oxides containing a cation with an ionic potential (ratio between charge and radius) of between 2.5 and 5.5. Suitable oxides include FeO, Fe<sub>2</sub>O<sub>3</sub>, NiO, MgO, and CuO. On the grounds of technology and economy, investigations were carried out on systems of orthophosphoric acid (H<sub>3</sub>PO<sub>4</sub>) and the oxides of iron and magnesium. The materials for iron-phosphate binders can include mill scale (from forges or rolling mills), iron ore concentrates, and ferruginous powder. The use of phosphate-bonded sands for the production of large carbon and alloy steel castings has reduced coremaking labor costs, cut the volume of knocking out and fettling operations and improved the dimensional accuracy of the castings. Phosphate-bonded core sands may also be adopted for the production of massive iron castings instead of cold setting sands with synthetic resin or soluble silicate binders. In this case, it should be possible to use either magnesium or iron oxides.

Zhukovskii, S.S.; Yunovich, Yu.M.; Nevskaya, O.E. *Sov Cast Technol* n 4 1987 p 44-47.

**092687 UNIFIED MOLDING SANDS FOR SMALL FOUNDRY MOLDS.** Trials were organized in the Verkhnedneprovsk Foundry to explore the scope for using clay-bonded molding sands with optimum physicochemical properties for machine molding. The mixtures have a minimum of constituents but include binders based on bentonite clays with agrimus additions. Agrimus is a waste product from the food industry arising from the pentose hydrolysis of corn stalks and consists largely of cellulose. The use of agrimus additions lowers the energy consumption in the molding shops and enhances the quality of the castings.

Bondarenko, V.I.; Kartashov, V.T.; Medvedev, Ya.I. *Sov Cast Technol* n 4 1987 p 48-49.

**092688 AQUEOUS WAX DISPERSIONS FOR RESIN-COATED SANDS.** In order to minimize the binder contents required to attain the specified mechanical and technological properties, the laws governing the spreading of resin over the sand grain surfaces were investigated. The resin flow kinetics were examined under a microscope (MNO-2). Granules of resin SF-015, in the form of spheres weighing 3 mg each, were dripped onto a preheated quartz sand substrate. As the resin touched the substrate, a motion picture camera was switched on to record its spread at a rate of 8 frames per minute. The droplet geometry was measured under a microscope (UIM-23), recording its linear and angular dimensions.

Radchenko, S.I. *Sov Cast Technol* n 5 1987 p 57-59.

**092689 RECYCLED COLD-SETTING MOLDING SANDS BASED ON FURITOL-30 BINDER.** Model tests have been carried out on the thermal and mechanical reclamation of cold-setting sands with furitol-30 binder. The furitol-30 is a silanized phenol-furane type resin. The thermal reclamation neutralizes the product (to pH=7.28) and brings the loss on ignition back to its original level.

Antonov, M.M.; Pechennikova, T.I.; Treiber, O.Yu.; Zheldakova, L.E. *Sov Cast Technol* n 8 1987 p 18-19.

**092690 LOW-TOXICITY COMPLEX BINDER.** The binder used to make hot-box cores is usually a 20% solution of urea in phenol spirit. Consequently, toxic fumes are given off and the low reactivity of phenol spirits prevent the equipment from being operated at maximum output rates. One way of improving working conditions and increasing equipment productivity is the development of complex binders with catalytic additives. The authors tested a range of catalytic additives for core sands based on complex hot-setting resins, which contain carbamide resin. The proposed core sands based on complex binders are used at the Khar'kov Tractor Works. The air in the working zones contains less phenol (2.5-fold reduction) and formaldehyde (2-fold reduction) and is free from cyanides and acrolein.

Sandalov, A.V.; Gumantsov, A.I.; Skobelina, Yu.P.; Temereva, V.V. *Sov Cast Technol* n 8 1987 p 20-22.

**092691 PHENOL-UREA-FORMALDEHYDE BINDER TOL-2 FOR HIGH-REACTIVITY CORE-SANDS.** Binders for use in the hot-box coremaking process should harden at moderate temperatures, have a high thermal durability comparable with phenol-formaldehyde resins and a high hardening rate comparable with urea-formaldehyde resins. The Kemerovo Chemical Research Institute has developed a new phenol-urea-formaldehyde resin grade TOL-2, a product of the two-stage condensation of formaldehyde, urea and phenol in an alkaline medium. The physicochemical properties of the new resin and the existing foundry-grade phenol-urea-formaldehyde resin SF-411 are compared.

Voroin, Yu.F.; Sincugov, Yu.D.; Koshelev, V.I.; Parfenov, Yu.A.; Kozlova, G.I. *Sov Cast Technol* n 8 1987 p 23-26.

**092692 GAS EMISSION FROM HOT SETTING BINDERS.** The VNIITmash Institute has collaborated with the VNIOT VTSPS Institute (Sverdlovsk) in an investigation of the quantitative aspects of gas emission during the preparation, baking and thermal degradation of core binders. The nature of the toxic substances associated with the use of binders USK-1 and KO is determined by the chemical constitution and structure of these products (petroleum still bottoms). During baking, core sands emit significant amounts of saturated aldehydes (formaldehyde), alcohols (methanol) and unsaturated aldehydes (acrolein). Binders SKT-11 and LST pollute the atmosphere with furfuryl spirit, furfural and formaldehyde. 4 refs.

Sincugov, Yu.D.; Sandalov, A.V.; Ogloblina, R.I.; Karavaeva, E.S. *Sov Cast Technol* n 8 1987 p 59-61.

**092693 ACOUSTIC EQUIPMENT FOR THE PREPARATION OF COMPLEX MOLDING SAND BINDERS.** Acoustic equipment produces uniform and stable binder suspensions which are of high quality and virtually immune to sedimentation. Molding sands with the requisite physicochemical and handling properties are produced at minimum consumption rates for bentonite and organic binders. The reductions are 20-30% on bentonite and up to 40% on binder USK-1. This leads to lower gas-forming capacity in the molding sands and lower mold and castings scrap rates.

Kiselev, V.K.; Burdenko, Yu.V.; Murkhortov, V.I. *Sov Cast Technol* n 8 1987 p 66-67.

**092694 INFLUENCE OF AIR HUMIDITY AND**

**TEMPERATURE ON THE SETTING OF COLD-HARDENING SANDS.** A study has been made of the strength-time relationships for cold-hardening sands and the effects of the humidity and temperature of the ambient atmosphere. The binder used was grade FF-1F resin, together with a 78% aqueous solution of acid hardener in amounts of 10-20% by weight of resin. Similar tests were carried out on sands bonded with soluble silicate and siloxanes. In order to harden cores and molds made from self-hardening sands at low ambient temperature, the binders and fillers should be preheated. A certain minimum binder and filler temperature is essential to the production of cold-hardening sands with a reduced binder/catalyst content (1.5-2 wt%). 4 refs.

Romashkin, V.N. *Sov Cast Technol* n 7 1987 p 23-26.

**092695 MOLD & CORE BINDERS KEEP PACE WITH INDUSTRY DEMANDS.** There are more than 20 different foundry resin binder systems currently used in the foundry industry. Total binder and individual system usage in North America are given. New process developments and refinements are directed at lowering emissions and improving casting dimensions, binder processing and reclamation. 3 refs.

Burditt, Michael F. (Modern Casting, Des Plaines, IL, USA); Carey, Paul R. *Mod Cast* v 78 n 6 Jun 1988 p 20-24.

## Compaction

**092696 MOLD DEFORMATION AND ACCURACY.** The behavior under load of molding sands in use can be described with the aid of the well-known elastoviscous model for the volume which deforms as it absorbs the external forces and the elastic potential model for the absorption of residual energy. The deformation conditions usually considered in molding sand investigations assume that the strains are independent of the time factor  $\tau$ . However, the elastoviscous bodies characteristically exhibit transient dynamic strain behavior. Authors have examined the results of tests on moist fluid sands under transient strain conditions, i.e., constant stress application with periodic deformation of the loading-load release type. The investigation has shown that sand control tests based on the ultimate strength alone do not meet the requirements of mold design. The working conditions applied to the sand must be covered by control tests on rigidity, which more truly reflects the real stress-strain conditions. This enables the mold design to be calculated rationally without unnecessary safety margins on strength and stability. 3 refs.

Plotnikov, N.R.; Vasenichev, V.P. *Sov Cast Technol* n 4 1986 p 26-28.

**092697 MECHANISM AND CONDITIONS OF SAND DEFORMATION DURING IMPULSE MOLDING PROCESSES.** There are two ways whereby molding sand is compacted in the impulse molding processes: under the action of static gas pressure with no expansion or acceleration, and under the action of the inertia of gas molecules following the explosive expansion of a gas/air mixture. Compaction by the second method is carried out with the aid of a device consisting of a special chamber or nozzle, a gas chamber, and a valve. The process can thus be accepted as effective and promising by virtue of its many advantages: self-accommodation to various casting configurations and mold dimensions; low sensitivity to variations in molding sand quality; high-quality mold production, and so on.

Vasil'kovskii, L.F. *Sov Cast Technol* n 3 1987 p 20-24.

## Cooling

**092698 CONTINUOUS COOLING OF WET FOUNDRY SAND USING A FLUIDIZED BED.** In order to establish the optimum cooling system for hot returned sand in metal casting processes, a mathematical model including simultaneous heat and mass transfer has been constructed. The study is especially directed towards clarifying the dynamical behavior of sand cooling in a

one-pass fluidized bed. Characteristics of both transient and steady-state bed temperature are explained by the model. A proposal is given on optimal operation which raises heat exchange efficiency in fluidization cooling of hot molding sand. (Edited author abstract) 13 refs.

Nomura, Hiroyuki (Toyoashi Univ of Technology, Toyohashi, Jpn); Terashima, Kazuhiko; Banno, Takeo. *Part Sci Technol* v 5 n 2 1987 p 207-218.

**092699 COOLING RETURN SAND WITH THREE-STAGE PROCESS.** Hot sand problems can be eliminated by evaporating water from the return sand. Such evaporative cooling is achieved by passing a counterflow of high-volume, low-velocity air through a curtain of damp, hot sand. Three-stage cooling is effective and efficient when flash cooling and premixing are accomplished on a belt conveyor and final cooling is performed in a rotary drum.

Didion, Michael S. (Didion Manufacturing Co, St. Peters, MO, USA). *Foundry Manage Technol* v 115 n 10 Oct 1987 p 44-45.

**Drying** See Also FOUNDRY PRACTICE—Molding.

**092700 DRY PNEUMATIC BENEFICIATION OF MOLDING SANDS.** The pneumatic method of beneficiating clay-bearing molding sands (without calcining) can be used for small quantities of sand when the organization of expensive hydraulic beneficiation facilities would be irrational, i.e., primarily in regions remote from the beneficiation plants (Siberia, the Far East). If the foundry already has the means for used sand reclamation, the introduction of pneumatic beneficiation can be much easier.

Osipov, M.A.; Stakhorski, A.V. *Sov Cast Technol* n 3 1986 p 42-43.

## Economics

**092701 ECONOMIC ROUTE MEEHANITE CASTINGS FROM POLYSTYRENE PATTERNS.** The polystyrene pattern manufacturing route is undoubtedly cheaper than conventional foundry techniques. Its use in the foundry can be divided into two distinct areas. First, the manufacture of relatively large castings on a one-off, or several-off, basis, using manually produced patterns, and secondly the production of repetition castings where the patterns are mass produced on specially developed machinery. The expanded polystyrene route for the production of castings, whether large one-offs, short or long series castings, offers significant economic benefits to castings buyers and users. The process also has considerable technical advantages compared with conventional sand casting, and offers engineering designers increased degrees of freedom.

Donaldson, E.G. (Int Meehanite Metal Co). *Cast World* v 20 n 2 Jul 1988 p 30-36.

**Hardening** See Also FOUNDRY PRACTICE—Carbon Dioxide Process.

**092702 USE OF SURFACTANTS TO ENHANCE THE PROPERTIES OF SOLUBLE SILICATE.** One promising method of improving the physicochemical properties of SS is by modification with surfactants. Authors have studied the effects of surfactant modification on surface tension, the wetting angle  $\theta$  and the viscosity of soluble silicates, since these variables determine the binder distribution in the sand. Surface tension measurements were taken by the maximum bubble pressure method in apparatus designed in conformity with the Rebind principle;  $\theta$  measurements on quartz were made by projecting the images of binder droplets on a quartz plate on to a screen; viscosity measurements were made in the VPZh-2 viscometer. Sands based on surfactant-modified soluble silicate have better physicochemical properties than those based on unmodified SS at the same binder content. If the sand properties are kept unchanged, modification reduces the knockout energy to 50-67% of the level for sands made with unmodified SS.

Morozov, I.V.; Chernyavskaya, M.G.; Kazakov, O.G. *Sov Cast Technol* n 3 1986 p 32-33.

## Mathematical Models

**092703 INFLUENCE OF SAND PREPARATION SYSTEM FACTORS ON CONSUMPTION OF MOLDING MATERIALS.** The influence of sand preparation system factors on the consumption of molding materials can be determined from a mathematical model which can predict the behavior of the system and its individual parameters. This article gives an evaluation of the scope for cost reductions in the preparation of unified sands for iron castings. It is based on a model of the molding sand balance. 2 refs.

Kvasha, F.S. *Sov Cast Technol* n 2 1987 p 60-64.

## Mechanical Properties

**092704 SAND TESTING ON SPECIMENS MADE IN HOT BOXES.** According to GOST 23409.7-78, sand specimens made in hot boxes for tensile testing must be prepared in a corebox on a sandblower rig under the conditions laid down in the technical norms for specific binders and sands. The corebox must be designed to produce figure-of-eight specimens 25 mm thick. The NIILitavtoprom Institute has developed a laboratory unit for the production of specimens by blowing into hot boxes. It has been found that identical specimens made in two units operating in parallel can give different tensile strength values for the same batch of sand. The authors therefore investigated the effects on tensile strength of varying the dwell time in the hot box, the cooling rate and the time lapse before testing. The specimens contained 100 parts sand and either 3.5% resin SF-480 and 0.5% catalyst M1 or 2.62% resin SFP-011L and 0.97% acetone.

Bekerman, F.A.; Morozov, I.V.; Sergeev, P.S. *Sov Cast Technol* v 11-12 1987 p 36-38.

## Mixing

**092705 APERCU SUR LES MOYENS DE DOSAGE A LA SABLIERIE: VERIFICATION ET CONTROLE.** [Sand Shop Proportioning Resources: Verification and Control]. Checks of sands prepared in the foundry by continuous mixers reveal large variations in the mechanical properties of these sands. In this article, simple ways of checking and monitoring the proportions are proposed. (Edited author abstract) In French.

Lahalle, J.P. (Cent Technique des Industries de la Fonderie, Fr). *Fonderie Fondeur Aujourd'hui* n 68 Oct 1987 p 19-21.

## Permeability, Mechanical

**092706 PERMEABILITY MEASUREMENTS ON MOLDING AND CORE SANDS.** Permeability measurement is one of the most widely used methods of testing molding and core sands in the laboratory. There are both standard and accelerated methods available. In both cases, permeability is defined by the formula  $r = Ql/\Delta pS$ , in which  $Q$  is the air flow rate ( $\text{cm}^3/\text{min}$ ),  $\Delta p$  the pressure drop across the specimen,  $\text{gf}/\text{cm}^2$  ( $1 \text{ gf}/\text{cm}^2 = 100$ ),  $l$  the length of the specimen ( $\text{cm}$ ) and  $S$  its cross-sectional area ( $\text{cm}^2$ ). An instrument with error correction has been developed by the Kharkov Branch of VNIIITmash and tested at the Usman Foundry Equipment Works. The instrument, Model 04314, has a measuring range of 30-300 units and an effective error limit of  $\pm 4\%$ . It is equipped with a 3-range digital indicator. It requires a 220-V mains supply but uses neither a bell nor a nipple.

Gomel'skii, Yu.S. *Sov Cast Technol* n 3 1986 p 41.

**Reclamation** See Also STEEL FOUNDRY PRACTICE—Molding.

**092707 CORESANDS CONTAINING RECYCLED SAND.** A pilot commercial unit for the pneumatic reclamation of used sands at 12 tons/hr has been set up in the Minsk Tractor Works. The quality of the reclaimed

sand is evaluated from its clay content ( $\leq 0.5\%$ ) and its loss on ignition ( $\leq 1\%$ ). The reclaimed sand is used for coremaking in the iron foundry. The following composition is specified for coresand with the mechanical properties:  $\sigma_{\text{comp}} = 12-14 \text{ kPa}$ ;  $\sigma_{\text{tensile}} = 1.2-1.4 \text{ MPa}$ ; water content 2.2-2.5%; gas permeability  $\leq 90$  units. A similar method to the above has been used to determine the relationship between the wettability of reclaimed sand and mixtures with fresh sand, and the quality of the reclaimed sand. Thus, by determining the wettability of the mixture of fresh and reclaimed sand (a point on the vertical axis) and that of the reclaimed sand alone, one can maintain in-process control over the proportion of reclaimed sand to be used.

Zhukovskii, A.S.; Suris, V.A. *Sov Cast Technol* n 3 1986 p 73-74.

**092708 WHEN CONSIDERING SAND RECLAMATION, PLAN FOR WASTE DISPOSAL.** Environmental restrictions on mining and preparation of new sand for foundries are increasing its cost. This and other factors thus make sand reclamation more attractive than ever for the typical foundry. The article outlines the steps involved in waste characterization and analysis including a materials balance evaluation.

Zayko, Robert E. (RMT Inc, Madison, WI, USA). *Foundry Manage Technol* v 115 n 9 Sep 1987 p 54, 56.

**092709 ECONOMIC PROBLEMS OF SAND RECLAMATION.** It is urgently necessary to draw up an All-Union standard procedure (or amend the existing procedure) with clearly defined rules for calculating the cost-effectiveness of sand reclamation in foundries, reflecting every cost factor. The relevant issues are: the actual costs of handling fresh sand, including, for example, the need for manual labor in winter, turn-around times for freight wagons, maintaining sand disposal dumps and possible extra charges for handling wastes which can harm the environment; the reduction in 'irrecoverable metal losses' when used sand is reclaimed rather than dumped; and the reduction or elimination of delays arising from interruptions in sand supply deliveries compared with the year before sand reclamation was introduced. 4 refs.

Fomin, V.N. *Sov Cast Technol* n 5 1987 p 20-22.

**092710 DRY MECHANICAL RECLAMATION IN MINTYAZHMASH PLANTS.** One major trend in the supply of foundry molding sands is the reclamation of used molding and core sands, with the basic purposes of restoring their grain structure and properties after use. The importance of reclamation in relation to the economic consumption of natural quartz sands is reflected in documents regulating the installation of sand reclamation facilities and a recycling policy. Accordingly, the TsNIIM Institute has developed the technology of dry mechanical sand reclamation from used silicate-bonded mixes and the range of equipment needed for its adoption.

Boichenko, A.S.; Gorfinkel, V.M.; Pyshmintsev, Yu.P. *Sov Cast Technol* n 5 1987 p 23-24.

**092711 INITIAL OPERATING EXPERIENCE IN DRY MECHANICAL RECLAMATION UNITS.** Production trials of the dry mechanical sand reclamation system and equipment have shown that it is a highly efficient system for the recycling of used molding sand mixtures after reclamation.

Mikheenkova, M.A.; Galibov, Yu.V.; Boichenko, A.S.; Menaker, M.N. *Sov Cast Technol* n 5 1987 p 25-29.

**092712 PNEUMATIC RECLAMATION OF USED SILICATE-BONDED SANDS.** The line operates under automatic control. The equipment is switched on before starting to knock out the castings, while the pneumatic regenerators and extraction system are switched on when

sufficient prepared material is available in the hopper. The technical characteristics of the line, with one and two regeneration systems in operation, are reported.

Fomin, V.N.; Zinchenko, Yu.A.; Kutovoi, N.L.; Gordeev, A.N. *Sov Cast Technol* n 5 1987 p 30-33.

**092713 RECLAMATION - THE MOST IMPORTANT MEANS OF REDUCING MOLDING SAND CONSUMPTION.** This report details the recommendations on optimum sand reclamation systems (I and II relating to molding and core sands, respectively), and shows that virtually every type of used sand can be reclaimed and recycled to the required property specifications. For instance, a bentonite-bonded sand can contain up to 20% of used resin-bonded core sand. Either mechanical or thermomechanical methods can be used. Reclaimed sand after mechanical stripping can be used in unified molding sands or special facing sands. After thermomechanical reclamation, the product can be used to make molds and cores of every type, as a substitute of identical quality to fresh sand. Minavtoprom undertakings have developed and introduced a technology and equipment for dry sand reclamation, which can handle virtually any type of used molding or core sand. 7 refs.

Poroshin, Yu. E.; Vodenikov, Yu. A. *Sov Cast Technol* n 5 1987 p 34-38.

**092714 ELECTROHYDRAULIC SAND RECLAMATION FROM USED SILICATE-BONDED MOLDING SANDS.** Electrohydraulic sand reclamation under conditions similar to those encountered in production plants was investigated in a specially developed laboratory rig in which the parameters of the discharge circuit could be varied widely. The ranges were: capacitor charging voltage 20-50 kV; capacitance 0.1-5  $\mu$ F; recurrence frequency 1.0-20 Hz; sand-water pulp volume 1-75 l. The rig was equipped with a two-beam recording oscillograph (S8-11) and an electrostatic kilovoltmeter (S-100). The number of discharge pulses was recorded in a PS-100 counter. The reclaimed sands retain no silicate reaction-products, and confirm the results of derivatographic, mineralogical, X-ray structural and electron microscope investigations. They furthermore confirm that after electrohydraulic regeneration, the reclaimed sands are substantially similar in composition to the original (clay content and water absorption capacity). The results demonstrate that aqueous pulps containing used silicate-bonded sands can be treated electrohydraulically to obtain high-quality reclaimed sands of similar physicochemical properties to the original basic sand. 2 refs.

Kukui, D.M.; Odinochko, V.F. *Sov Cast Technol* n 5 1987 p 43-45.

**092715 USED SAND RECLAMATION IN A NON-FERROUS METALS FOUNDRY.** The wet reclamation technology described yields high grade reclaimed sands from the used sands from nonferrous metals foundries, including clay-bonded molding sand mixes and resin-bonded coresand mixes. The final stage of treatment in electrostatic corona-discharge drum separators completely eliminates residual nonmagnetic metallic impurities. The technology is designed for the use of equipment already in commercial production.

Bulygin, I.F.; Gabdulkaev, R.L.; Krysova, L.P. *Sov Cast Technol* n 5 1987 p 62.

**092716 REGENERATION OF WASTE MOLD SAND.** Two reclamation methods - a dry method and a wet method - are available which make it possible to reuse waste sand discharged from foundries in large quantities. Japan has widely adopted the dry method, in which secondarily generated wastes are easily treated and the recovered sand has a higher purity. Our Yokohama Plant, however, completed a water-washing type reclamation facility, which is equivalent to the wet method, because of the small area of land available and to minimize the initial investment. The facility reclaims the entire amount of waste sand generated in the plant, which is then reused as raw sand material for core and main molds. It has been proved that the sand recovered by the wet method, when

applied to a cold box, (becoming popular in recent years), is higher in strength than new sand, although the purity of the sand recovered by this wet method is lower than that of sand recovered by a dry method. (Author abstract)

Tanaka, Toshihide (Nissan Motor Co, Yokohama, Jpn). *Conserv Recycling* v 10 n 4 1987 p 253-263.

**092717 MODEL L495/24,008 PNEUMATIC SAND RECLAMATION UNIT.** At the request of the agricultural machinery ministry, the VNIITmash Institute has finalized the technical documentation for a prototype production unit based on the experimental unit for used molding sand reclamation installed at the Minsk Tractor Works (MTZ). The unit consists of a supply bunker, an acceleration pipeline, upper and lower cleaning sections, and a suction manifold with drum screens. The drum screens discharge reclaimed sand and screenings separately and are linked to an air extraction system.

Berezhnoi, S.V.; Demenkov, G.G.; Kuznetsov, V.V.; Shmorgun, Ya.Sh. *Sov Cast Technol* n 8 1987 p 51-52.

## Recycling

**092718 THERMAL AND MECHANICAL RECYCLING OF USED FOUNDRY SANDS.** A dry process for recycling used foundry sand has been developed. This process can be used for treating many kinds of binding materials such as, for example, clay, synthetic resins and cement. It consists of a versatile, economical and nonpolluting recycling technique for foundry sands which can be applied to all foundries which have casting molds based on sand. The significant processing stages are magnetic separation, fluid bed treatment and counterflow baffling. The recycling sand has the quality of new sand; an extensive reuse of by-products in other fields of industry appears to have good prospects, so that only extremely low quantities have to be disposed of. Another important factor of using this process is the recovery of about 50% of the heat used. (Edited author abstract) In German and English.

Bauer, H. *Aufbereit Tech* v 8 Aug 1987 p 456-462.

## Rheology

**092719 SIMULATING THE RHEOLOGICAL PROPERTIES OF MOLDING SANDS.** The basic data for synthesizing a rheological model of molding sands can be derived from stress-strain curves recorded in simple shear. The author used a plastometer operating on the principle of axial shear between coaxial cylinders. Tests can be carried out at different shearing rates in sands compacted to different degrees, and complex stress distributions can be set up in the specimens during testing. The stress-strain curves are automatically recorded on the chart of a two-coordinate potentiometer. The key to rheological simulation is the selection of a combination of elementary models compatible with the postulated adequacy conditions in respect of the description of experimental data. Having found the rheological model for a molding sand, the computer can be used to select optimum compaction conditions or sand compositions for a given molding process. 5 refs.

Avdokushin, V.P.; Doroshenko, S.P.; Surguchev, E.A.; Akhonin, S.V. *Sov Cast Technol* n 3 1986 p 23-25.

**092720 AUTOMATED PLANNING OF OPTIMUM MOLDING SAND COMPOSITIONS.** There is an urgent need nowadays to adopt a unified procedure for the twin problems of automated planning, i.e., to optimize the composition and properties of the molding sand and the molding conditions to suit the operating characteristics of a given molding machine, and conversely to optimize the molding machine characteristics to suit molding sand of a given composition and properties. The proposed procedure in conjunction with the use of computers to interpret the oscillograms, the calculation of optimum sand compositions, and continuous composition correction under production conditions, is a key link in automatic production control (ASU TP) systems for foundries.

*Technol* n 3 1986 p 66-67.

## Structure

**092721 ON THE SPHEROIDAL MODEL OF MOLDING SAND STRUCTURE.** Discussions of the strengthening mechanism in cores and molds, and solutions to practical technical problems, are usually based on the spheroidal model. This describes molding sand as a system of spheres of identical diameter bonded together at contact faces. The size and shape of the contact zones depend on the capillary forces which draw the liquid mixture into the contact areas. The spheroidal model has been used to derive formulas for calculating sand strength. It is applied whenever the strengthening and weakening of molds and cores is studied theoretically or experimentally. It follows from the general views on the strength of disperse systems that the strength of molding sands is actually influenced by the basic characteristics of the spheroidal model such as the number of contact areas in unit volume, the size of the contact zones and their strength, regarded as a combination of adhesion and cohesion. 4 refs.

Zhukovskii, S.S.; Romashkin, V.N. *Sov Cast Technol* n 3 1986 p 20-22.

## Testing

**092722 STUDY OF THE LIFESPAN OF COLD-SETTING AND PLASTIC SELF-SETTING SANDS.** The newly developed test and testing instrument can be used in the laboratory and production shops, not only to monitor the lifespan and investigate the properties of CS and PSS sands but also for the quality control of raw materials. The scientific uses of the instrument embrace the entire kinetics of sand behavior from the moment of preparation. PRS instruments are already in use at the Nevskii Zavod, KhTZ (S. Ordzhonikidze) and Stankolit. 2 refs.

Volkov, A.V.; Borsuk, P.A. *Sov Cast Technol* n 3 1986 p 26-29.

**092723 NEW CONCEPTS OF GREEN SAND TECHNOLOGY - PART I.** Technology advances in green sand molding machines are outpacing the sophistication of conventional sand testing practices. For instance, green strength alone is an inadequate measure of mold quality and can lead to interpretation errors. Molding sands need to be monitored differently today than in the past. Innovative green sand testing technology is available to match the capabilities of today's state of the art molding equipment.

## Drying

**092724 DEWATERING OF QUARTZ SAND ON STEAM-HEATED HORIZONTAL SAND FILTERS.** Thermal drying and mechanical dewatering with dewatering silos or vacuum filters to 5-15 wt% residual moisture content, depending on grain size, the economical dewatering of sand to constant values 3 wt% water content is of great interest. The Dorr-Oliver horizontal sand filter with steam heating has proved to be excellently suited for this task. (Edited author abstract) In German and English.

**Marketing See GLASS INDUSTRY—Materials.**

## Mathematical Models

**092725 COMPUTER MODEL FOR BARCHAN-DUNE MOVEMENT.** Barchan sand dunes are one of the most recognizable desert landforms. They have been the subject of considerable mathematical and physical research. Research for this paper set out to take these previous results, and formalize them into a computer model. The model simulates the movement of a barchan dune of any morphology under a variety of wind regimes, and produces graphic and textual output. Limited testing suggests the model produces rates of movement comparable with those observed in the field. The program is written in Turbo Pascal to run on IBM PCs and compatibles. It is believed that the program will be at its most useful as a contribution to geomorphology laboratory classes. (Author abstract) 11 refs.

## Surfaces

**092727 ACTIVATION OF QUARTZ AGGREGATE BY NITRIC ACID AND ITS INFLUENCE ON THE HARDENING PROCESS AND THE STRENGTH OF CEMENT-SAND CONCRETE.** A study was made of the activation of the quartz sand by solutions of nitric acid and the effect of this activation on the hardening kinetics and the strength of the cement-sand concrete. Experimental evidence shows that activation of the surface of the quartz sand by nitric acid leads to a significant increase in the exchange capacity relative to calcium ions and the partial hydrophobization of the surface. It is established that the significant influence of the surface of the quartz sand on the kinetics of the hardening and the strength of the cement-sand composite, and the linear dependence of the strength of this composite on the exchange capacity of the aggregate. 14 refs.

## Analysis

**092729 SEISMIC STRATIGRAPHY OF EARLY PENNSYLVANIAN MORROWAN SANDSTONES, MINNEOLA COMPLEX, FORD AND CLARK COUNTIES, KANSAS.** The oil fields of the Minneola complex in southwest Kansas produce from north-west-southeast-trending marine sandstones of Morrowan age. Reservoir quality stratigraphic traps developed at the intersection of sandstone trends and topographic lows or channels on the underlying eroded Mississippian surface. Electric logs in the Ladd-8 Norton discovery well revealed that an expanded Morrow section consisting of sandstone and shale had been deposited in lows on the underlying eroded Mississippian surface. Modeling indicated that the addition of this low-velocity elastic material within these channels caused a variety of seismic anomalies, the distribution of which guided subsequent exploration and development drilling. These seismic anomalies are associated with topographic lows on the Mississippian unconformity surface rather than the productive sandstones. These anomalies vary according to the thickness of sediment deposited within the erosionally low areas, the varying geometry and lithologies of these deposits, variations in overlying sediments, and the angle at which the seismic line is shot across the lows. (Edited author abstract) 18 refs.

Clark, Stacy L. (Ladd Petroleum Corp, Tulsa, OK, USA). *AAPG Bull* v 71 n 11 Nov 1987 p 1329-1341.

**092730 TECTONIC, SEDIMENTARY, AND SEISMIC MODELS FOR D SANDSTONE, ZENITH FIELD AREA, DENVER BASIN, COLORADO.** The Zenith field is a recently developed area that contains significant reserves in the D sandstone, with minor production from the J sandstone, with minor production from the J sandstone. The productive D sandstone in the Zenith field has previously been interpreted as a distributary channel deposit. A new depositional environment for the D sandstone is proposed based on detailed mapping that suggests the D productive sandstones are of channel origin within a valley-fill complex. Analysis of seven stratigraphic intervals clearly show that paleostructure influenced D depositional patterns. Seismic models were constructed and seismic data were examined in the Zenith field area to determine if thick D valley-fill deposits are detectable. An analysis of the Dakota interval on the model and seismic data shows an amplitude anomaly present in the position of the D valley-fill deposits. (Edited author abstract) 13 refs.

Sonnenberg, Stephen A. (Bass Enterprises Production Co, Denver, CO, USA). *AAPG Bull* v 71 n 11 Nov 1987 p 1366-1377.

**092731 SEQUENCE STRATIGRAPHY AND DEPOSITIONAL CONTROLS IN LATE PROTEROZOIC-EARLY CAMBRIAN SEDIMENTS OF AMADEUS BASIN, CENTRAL AUSTRALIA.** The Amadeus basin is an isolated intracratonic basin at the center of the Australian continent which, because of its location and geometry, provides an ideal opportunity to investigate depositional controls. The Arumbera sandstone was deposited as two major depositional sequences in a shallow marine and deltaic or coastal-plain setting, similar to that of the Devonian Catskill delta of North America. Sediment was supplied from the southwest by heavily laden, braided streams. In the deep subbasins, the Arumbera Sandstone forms a continuous depositional unit across the Proterozoic-Cambrian boundary. The final geometry of the Arumbera Sandstone and the nature of its sediments were determined largely by local subsidence rates. Other variables, such as climate, the lack of vascular plants, and the uplifts of the source area were also factors in controlling deposition. (Edited author abstract) 30 refs.

Lindsay, John F. (Bur of Mineral Resources, Canberra, Aust). *AAPG Bull* v 71 n 11 Nov 1987 p 1387-1403.

**092732 REGIONAL SEDIMENTOLOGY AND PETROLEUM GEOLOGY OF MARINE, LATE BATHONIAN-VALANGINIAN SANDSTONE IN THE NORTH SEA.** A large number of marine, late Bathonian-Valanginian sandstone units have been identified in the North Sea, north of the Mid North Sea High. This paper discusses their complex areal distribution and outlines sedimentological models. The sandstone formations are interpreted as shallow marine, transgressive and regressive units interbedded with beach, lagoonal and coastal plain deposits. Coarse grained scarp fed fans occur along fault-controlled rift margins. The total proven recoverable reserves in these sandstone reservoirs are  $2.3 \times 10^9$  ton oil equivalent, of which approximately one third is oil. (Edited author abstract) 20 refs.

## Compaction

**092733 COMPACTION AND POROSITY EVOLUTION OF PLIOCENE SANDSTONES, VENTURA BASIN, CALIFORNIA.** Sandstones of the Pico and Repetto formations were studied to quantify the processes involved in compaction and to determine the porosity evolution of the beds during burial. Stratigraphic studies and graphic porosity-depth plots suggest that the sample's maximum burial depths were approximately 10000 ft deeper than the present-day depths of 850-13000 ft. Assuming sands had 40 percent initial porosity, the sandstones that are at present most deeply buried lost a total absolute porosity of 26 percent by all compactional processes, which includes 14 percent by grain rearrangement and 6 percent each by pressure solution and ductile grain deformation. Compaction was almost entirely the result of overburden pressure and was not noticeably retarded in overpressured zones, suggesting that overpressures developed after maximum burial was achieved. Secondary porosity averages 20-40 percent of the total thin-section porosity. (Edited author abstract). 47 Refs.

Wilson, John C. (Univ of Texas at Austin, Austin, TX, USA); McBridge, Earle F. *AAPG Bull* v 72 n 6 Jun 1988 p 664-681.

## Composition Effects

**092734 EFFECT OF SALT COMPOSITION ON CLAY RELEASE IN BERECA SANDSTONES.** The effect of salt composition of fluid injected into clay-bearing Bereca sandstones on the water-sensitivity phenomenon has been studied. Experiments were carried out with solutions of sodium and/or calcium ions, which are the ions commonly found in the formation. Freshwater flooding of sandstones previously exposed to sodium salt solutions results in the release of clay particles and a drastic reduction in permeability. The permeability reduction is lessened, however, when calcium ions are also present in the salt solution. Formation damage is virtually eliminated when the solution composition is adjusted to give calcium surface coverages greater than a critical value of 75%. (Edited author abstract) 29 refs.

**092735 EXPERIMENTAL AND THEORETICAL STUDIES ON STRAIN SOFTENING BEHAVIOR OF ROCKS.** In order to reinvestigate the strain softening behavior of rocks, firstly, conventional triaxial tests for Ainoura sandstone were performed by using the stiff

testing machine. It is an interesting test result that the strain softening behavior could not be controlled stably because of brittleness when confining pressure exceeds 30MPa rather than in uniaxial. The comparison between the local strains with the strain gauges and the apparent strain with the displacement transducer in the strain softening and residual regions manifests that the latter strain reflects the plastic shear deformation along the fracture plane formed in the specimen. It means that the strain softening behavior is not an intrinsic property of material but depends on the structure of the specimen. Secondly, a model for the strain softening behavior was based on the test results and expressed by equation. The present experimental result that softening stress increased with confining pressure reasonably explains the unstable strain softening behavior under high confining pressure. In Japanese. 19 refs.

## Porosity

**092736 MICROPOROSITY STUDY OF VILLAMAYOR SANDSTONE (SALAMANCA, SPAIN).** In the clay fraction of the Villamayor Sandstone (Salamanca, Spain), pores with a diameter close to 3 nm are predominant. These pores are in the mesoporosity range and micropores are absent. On heating in vacuo at 470 K no significant change in the pore size distribution was observed, but the specific surface area decreased by ca. 10%, probably due to sintering of the particles on loss of water and surface hydroxyl groups. Treatment with humid nitric oxide for 20 h at this same temperature decreased the contribution by these pores but increased that from pores in the range 5-15 nm diameter. No change was observed, however, in the X-ray diffraction diagram, indicating that changes upon nitric oxide treatment affect isolated, non-periodical portions of the crystals. (Edited author abstract) 16 refs.

Del Arco, Margarita (Univ de Salamanca, Salamanca, Spain); Carballo, Ana M.; Holgado, Maria J.; Martin, Cristina; Rives, V. *Appl Clay Sci* v 2 n 4 Sep 1987 p 375-383.

**092737 GENERATION OF WATER-SOLUBLE ORGANIC ACIDS FROM KEROGEN DURING HYDROUS PYROLYSIS: IMPLICATIONS FOR POROSITY DEVELOPMENT.** Concentrations of organic acids ranging up to several thousand parts per million have previously been found in oil-field waters. These acids are of interest because of their potential to enhance porosity by the dissolution of carbonates and aluminosilicates. They are believed to be generated from organic geopolymers (kerogen) in the late-diagenetic-early-catagenetic stage of thermal maturation. During the course of artificial maturation experiments in which kerogens of varying type were heated in the presence of water (so-called 'hydrous pyrolysis') and different minerals, the distribution and abundance of low molecular weight water-soluble acids were determined by gas chromatography and gas chromatography-mass spectrometry. Preliminary results suggest that significant quantities of mono- and di-carboxylic acids are produced during hydrous pyrolysis. The amounts and types of acid appear to vary as a function of kerogen type, maturity and mineralogy. Implications of these findings regarding the development of secondary porosity are discussed. (Author abstract) 18 refs.

**092738 REPLACEMENT OF SANDSTONES BY URANIFEROUS HYDROCARBONS: SIGNIFICANCE FOR PETROLEUM MIGRATION.** Hydro-

carbons (bitumens sensu lato) in sandstones have been recorded in several instances to have partially replaced their host rock, including quartz grains. Many replacive hydrocarbons are uranium-rich: associated non-uraniferous hydrocarbons are not replacive. Uranium is transported as carbonate complexes, which may be decomposed by organic acids to yield  $UO_2^{2+}$  ions and  $CO_2$ . The  $UO_2^{2+}$  will be absorbed onto hydrocarbons before reduction to a mineral phase, generally uraninite; and the  $CO_2$  may be aggressive towards the silicate grains of the host sandstone. Accretionary nodules of replacive uraniferous hydrocarbon in red beds (e.g. at the cores of reduction spots) can provide valuable information about petroleum migration. They occur particularly in the vicinity of faults, and may record the interactions between metal-rich groundwaters and hydrocarbons leaking along a fault from an underlying reservoir. A trial study in Devonian sandstones of Easter Ross successfully traced a hydrocarbon-bearing sandstone reservoir from an occurrence of uraniferous hydrocarbon nodules. (Author abstract) 55 refs.

**092739 FRACTAL POROUS MEDIA. II: GEOMETRY OF POROUS GEOLOGICAL STRUCTURES.** Some geological structures are analyzed and found to be fractal. An interesting feature is the very large range of scales involved. The spreading dimension is also measured for some of them. The consequences of these measurements on the analysis of transport processes in porous media are presented. The existence of fractal structures multiplies the variety of actual porous media. (Edited author abstract) 21 refs.

## Quebec

**092740 DIVERSE OCCURRENCES OF GALENA-CEMENTED SANDSTONES IN THE PALEOZOIC, NORTHERN APPALACHIANS, QUEBEC.** Four occurrences of galena-cemented sandstones in the Lower St. Lawrence - Gaspésie area are described. They constitute a new, insufficiently explored type of deposit in Quebec. One mineralized body, a minor occurrence, is hosted in Lower Devonian rocks deposited in an estuarine, intertidal river channel during a marine regression. Major cements are dolomite and sulfides. Another occurrence, a drilled prospect, is hosted in upper Silurian rocks deposited unconformably on Cambro-Ordovician basement during a marine transgression. With galena and quartz as main cementing minerals, it is similar to some economic sandstone-lead deposits. A third and fourth, a drilled prospect and a minor occurrence, are hosted in Upper Cambrian rocks deposited on continental slopes. (Edited author abstract) 22 refs.

## Testing

**092741 TRIAXIAL TESTING OF BRITTLE SANDSTONE USING A MULTIPLE FAILURE STATE METHOD.** The first phase of a recent research program undertaken to investigate sandstone/methane outbursts in coal bearing rocks required the use of a sandstone reference material in the development and trial of the testing procedures to be used. The International Society for Rock Mechanics (ISRM) multiple failure state method is attractive because an approximate strength envelope can be determined from a single specimen. In this test program however the brittle nature of the reference material made control of failure by monitoring axial strain (the ISRM method) impossible; specimens always failed at the first, low or zero confinement, stage. An alternative method of detecting imminent failure in the specimen was developed

and applied, yielding results almost identical to those obtained by conventional single state testing. (Edited author abstract) 3 refs.

Cain, Peter (CANMET, Sydney, NS, Can); Yuen, Clement M.K.; Le Bel, Guy R.; Crawford, Adrian M.; Lau, Donald H.C. *Geotech Test J* v 10 n 4 Dec 1987 p 213-217.

**092742 STRENGTH AND DEFORMATION BEHAVIOUR OF SANDSTONES.** Triaxial test results up to 125 kg/cm<sup>2</sup> on four Indian sandstones have been presented in this paper. The deformation characteristics in terms of modulus of elasticity and Poisson's ratio and their variation with confining pressure have been discussed. The modulus parameters K and n have been evaluated for predictions at high confining pressures. Further, the strength criterion proposed by the authors is also discussed and used in the strength predictions for these sandstones. (Author abstract) 13 refs.

## Texas

**092743 CEMENTATION AND BURIAL HISTORY OF A LOW-PERMEABILITY QUARTZARENITE, LOWER CRETACEOUS TRAVIS PEAK FORMATION, EAST TEXAS.** One problem in interpreting diagenetic conditions in older basins is identifying the timing of diagenetic events except in relative terms. In this study of the Lower Cretaceous Travis Peak Formation in East Texas, the authors used a combination of standard petrography and stable-isotope geochemistry, and knowledge of the burial and thermal history of the formation to identify the authigenic cements in the formation, interpret the timing of their formation, and infer the conditions under which the cements precipitated. Results suggest that much of the cementation occurred in deeply circulating hot meteoric water. 43 refs.

## Analysis

**092745 FINITE ELEMENT PACKAGE FOR THE ANALYSIS OF SANDWICH CONSTRUCTIONS.** An approach to the finite element analysis of sandwich constructions is proposed which is based on a built up element technique. Finite element models are formulated from an assemblage of simple plane elasticity and special beam elements. Such independent specification of core and facings provides a versatile means of defining sandwich properties and response, allowing the analysis of diverse structural forms with a single computer package. The

program is particularly suitable for the examination of sandwich beams with transversely soft cores. Such properties are common in cladding panels which use plastic foams as insulation. (Edited author abstract) 13 refs.

O'Connor, D.J. (Univ of Ulster, Antrim, North Irel). *Compos Struct* v 8 n 2 1987 p 143-161.

## Bonding

**092746 STUDY OF THE TRANSIENT LIQUID PHASE BONDING PROCESS APPLIED TO A Ag/Cu/Ag SANDWICH JOINT.** Transient liquid phase (TLP) bonding involves the formation of a liquid layer between two adjoining pieces and the formation of a solid bond as the liquid disappears during annealing at a constant temperature. In this study, a model Ag/Cu/Ag sandwich joint associated with a simple eutectic phase diagram was used to study the different stages of this process. The results confirm that the TLP bonding is a diffusional process occurring in distinctive stages. The two most important stages are the widening and homogenization of the previously dissolved liquid interlayer, and the subsequent solidification and shrinking of the interlayer. Whereas the former stage involves diffusional processes in the solid phase. A modeling approach has been explored which shows that in most eutectic systems there exists an optimal bonding temperature corresponding to the shortest time needed for complete solidification. The use of an alloy close to the eutectic composition as an interlayer material shortens the TLP process. (Edited author abstract) 13 refs.

## Crack Propagation

**092747 SANDWICHED LAYER CONTAINING AN INTERFACE CRACK.** Stresses around an interface crack in the elastic layer sandwiched between two elastic half-planes are determined. The crack surfaces are loaded by an equal and opposite normal stress. It is assumed that no contacting regions exist near the crack tips. Application of the Fourier transform technique reduces the problem to that of solving a pair of dual integral equations. To solve the integral equations, the crack surface displacements are expanded in trigonometrical functions accompanied with the unknown coefficients. To solve these unknowns, the Schmidt method is used. The stress intensity factors are calculated numerically for some combinations of Young's modulus ratio of the composite materials and the crack length. (Author abstract) 7 refs.

**Deformation** See DOMES AND SHELLS—Elastoplasticity; PLATES—Buckling.

## Design

**092748 OPTIMAL SANDWICH BEAM DESIGN FOR MAXIMUM VISCOELASTIC DAMPING.** Three-layer sandwich beams, made of two elastic outer layers and a viscoelastic layer sandwiched between them, are considered as damping structural elements. A sixth-order equation of motion with complex coefficients of a sandwich beam in free vibrations is reviewed and solved numerically for a large variety of boundary conditions. The solution is used later as part of an optimal design program. An equality constrained minimization algorithm is modified and used to obtain optimal design of damping sandwich beams subjected to inequality design constraints. The use of the program is demonstrated by solving two design problems. (Author abstract) 13 refs.

Lifshitz, J.M. (Technion, Haifa, Isr); Leibowitz, M. *Int J Solids Struct* v 23 n 7 1987 p 1027-1034.

## Heat Transfer

**092749 SANDWICH PLATE UNDER THERMAL IMPACT.** The extensive application of laminated structure elements in industry arouses interest in determining the temperature fields therein and in describing their dynamic behavior under thermal force action. An expression is obtained for the temperature field and the fluctuations excited by a thermal impact are investigated. (Edited author abstract) 9 refs.

Kharitonov, V.V. (Belorussian Inst of Railroad Transport Engineers, Gomel, USSR); Starovoitova, T.A.; Starovoi-tov, E.I. *J Eng Phys* v 52 n 6 Jun 1987 p 734-740.

**Mathematical Models** See Also BEAMS AND GIRDERS—Vibrations.

**092750 COUPLING BETWEEN SYMMETRIC AND ANTISYMMETRIC MODES IN SHELLS OF REVOLUTION.** An analytical-numerical procedure is applied for composite laminated shells of revolution in investigating the coupling effect between symmetric and antisymmetric modes and its overall influence. The numerical solution is based on separating the variables in Fourier series in the circumferential direction and conical finite elements in the meridional direction. The contribution of the coupling effect is examined by means of parametric analysis. (Author abstract) 11 refs.

## Mechanical Properties

**092751 TENSILE PROPERTIES OF STAINLESS STEEL-CLAD ALUMINIUM SANDWICH SHEET METALS.** The yield strength, tensile strength, strength coefficient, uniform elongation, strain hardening exponent and strain rate sensitivities have been analyzed on the basis of the fact that the flow stresses of the sandwich sheets follow the rule of mixtures, an average of component properties weighted by the volume fractions. The rule of mixtures can be applied to the tensile strengths and strength coefficients whereas the yield strengths do not follow the rule. The force weighted average rule, an average of component properties weighted by volume fractions and forces, can be applied to uniform elongations, strain hardening exponents and strain rate sensitivities of the sheets. (Edited author abstract) 5 refs.

Lee, Dong Nyung (Seoul Natl Univ, Seoul, South Korea); Kim, Yoon Keun. *J Mater Sci* v 23 n 4 Apr 1988 p 1436-1442.

**092752 HIGH PERFORMANCE SANDWICH PANELS MADE FROM BRAIDED TUBES.** A light-weight, high performance sandwich panel has been developed using thin walled braided tubes as the core material. The panels have certain specific advantages over conventional honeycomb sandwich panels including superior skin-core bonding, integral conduit systems and self-draining thereby avoiding moisture accumulation. A short manufacturing process leads to a cost effective product. The technology of the tube production is not material specific so any reinforcing fiber can be used in conjunction with a large number of resin systems including thermoplastic resins. The braided tubes used as the core can be produced in a wide variety of cross-sectional shapes and sizes so the panels can be designed to meet various specific functions. (Author abstract).

Williams, Dennis J. (Courtaulds Research, Coventry, Engl); Ajibade, Funsho. *SAMPE Q* v 19 n 4 Jul 1988 p 35-39.

## Nondestructive Examination

**092753 CHECK OF BOND QUALITY OF METAL HONEYCOMB BY NONDESTRUCTIVE TESTING.** Described in the paper are the sensitivity and reliability for detecting unbonded fault in the metal honeycomb structure of single skin with the bond strength checker type

QJ-75, the check of the honeycomb structure with back-up plate and the make of the simulated fault in a bonded sample. (Author abstract) In Chinese.

## Pressure Effects

**092754 EFFECT OF CONTACT AREA SHAPE AND PRESSURE DISTRIBUTION ON MULTI-LAYER SYSTEMS RESPONSE.** Numerical analysis of stresses, strains, and displacements in multilayer systems for any shape of contact area and pressure distribution is presented. The scheme developed for microcomputers is made of two programs: one for evaluating the stresses and deformations under a point load and the second for performing the numerical integration of the point load solution. Results obtained by using the scheme for the uniformly distributed pressure, Boussinesq, and three-layer system cases were compared to those of analytical and other numerical solutions. Results for a rectangular contact area and nonuniform pressure distribution are presented. The effect of the contact area and pressure distribution shapes on the design strains is illustrated and discussed. The scheme presented is preferable to the 3-D finite element analyses. It dispenses with the use of mainframe computers and is highly accurate. (Edited author abstract) 7 refs.

Uzan, Jacob (Technion, Israel Inst of Technology, Haifa, Isr); Sides, Arie. *Trans Res Rec* 1117 1987 p 21-24.

## Stability

**092755 STABILITY OF ORTHOTROPIC SANDWICH SHELLS OF REVOLUTION UNDER NONAXISYMMETRIC TEMPERATURE-FORCE LOADING.** The stability problem of sandwich shells of revolution subjected to nonaxisymmetric temperature-force loads is solved in this paper. The presence of nonaxisymmetric components of the temperature-force loading complicates the structure stability investigation substantially. A variation of nonlinear thin shell theory in a quadratic approximation is used in this paper for small elongations and shears in the projections on the axes related to the undeformed coordinate surface. 9 refs.

Fomichev, Yu.I.; Perevozchikova, V.M.; Bakulin, V.N. *Sov Appl Mech* v 22 n 12 Dec 1986 p 1155-1160.

## Stresses

**092756 ANALIZA STATECZNOSCI TROJWARSTWOWEJ POWLOKI WALCOWEJ PRZY OBCIAZENIACH ZLOZONYCH.** [Stability of Sandwich Cylindrical Panel under Combined Load]. The paper presents the analysis of stability loss for the open sandwich cylindrical shell with light weight core, and free-supported at all edges. Using the nonlinear solution the upper and the lower critical load values are obtained for panel loaded simultaneously by compression forces acting along shell generated by shear forces uniformly distributed at the shell edges, and also by uniform radial external pressure. The stability equilibrium regions, as load parameters, of the considered shell in three-dimensional coordinate system are elaborated. The influence of some geometrical and physical parameters on critical load values at the stated combined load is also investigated. The results of calculations are presented on graphs. (Author abstract) 11 refs. In Polish.

**092757 BUCKLING ANALYSIS OF COUPLED SHEAR WALLS BY THE MULTI-LAYER SANDWICH MODEL.** It is well known that the continuum model of a shear wall is a sandwich beam which consists of 'stiff' and 'soft' layers. The paper presents the differential equation system of the multi-layer sandwich beam, and gives a method and closed formulas to determine the

critical load in case of a concentrated force acting on the top of the beam. The paper also shows that the critical load of a multi-layer sandwich cantilever is - to a close approximation - equal to the critical load of a triple-layer sandwich beam, i.e. a sandwich with thick faces. (Author abstract) 9 refs.

Kollar, Laszlo P. *Acta Tech (Budapest)* v 99 n 3-4 1986 p 317-332.

**092758 ON THE RULE OF MIXTURES FOR FLOW STRESSES IN STAINLESS-STEEL-CLAD ALUMINIUM SANDWICH SHEET METALS.** Sandwich sheets of (304 stainless steel)-aluminum-(304 stainless steel) were fabricated by rolling. The flow stresses followed the mixture rule which is an average of component properties weighted by volume fractions, even when transverse stresses were calculated to develop in the component layers due to their different anisotropic plastic behaviour. Such flow stresses are attributed not to negligibly small transverse stresses compared with longitudinal stresses but to the compensation effects of increased and decreased longitudinal stresses due to tensile and compressive transverse stresses which developed in the different component layers. (Edited author abstract) 13 refs.

**092759 STRESS CONCENTRATIONS OF A SANDWICH PLATE WITH A HOLE OR NOTCH.** This paper presents the characteristics and some example data of the stress concentrations of a sandwich plate in a wide sphere of dimensions in order to determine the optimum design of a sandwich plate with a hole or notch. In analyzing the structural sandwich plate, we apply two bending theories, of which we name one the simple bending theory and the other the advanced bending theory. By using FEM analysis, which is based on these two bending theories, we determine stress concentrations of a sandwich plate, taking into account both the accuracy and cost efficiency of the calculations. We also examine the stress concentrations and reveal the characteristics of the stress concentrations under two types of bending loads: anticlastic bending load and cylindrical bending load. To show examples of stress concentrations of a sandwich plate, we use the simple bending theory under the anticlastic bending load. (Edited author abstract) 4 refs.

Kim, Yeonseung (KAERI, South Korea); Nagao, Hiroshi. *JSMI Int J Ser 1* v 31 n 1 Jan 1988 p 42-49.

**092760 POINT CONCENTRATIONS IN THICK-FACED SANDWICH BEAMS.** The analysis of thick-faced sandwich beams is reviewed with particular emphasis on responses within the region of point loading. Examination of solution equations for three- and four-point loading cases shows that point effects are highly localized, dissipating fully with a critical span away from the point load. The critical span length is constant, and stress concentrations and displacement distortions have constant magnitude when presented in terms relating to sandwich cross-sectional geometry and material properties. Facing stress is magnified below the landing with an associated complementary reduction in core shear stress. Local face bending promotes reduction in overall displacement. Point effects are shown to be the major source of errors in the determination of sandwich properties by flexural testing methods. An alternative approach to such tests is suggested. A conjugate point method, which uses displacement positions outside the influence of the point effects, is shown to be much more accurate. (Author abstract) 13 refs.

## Structural Analysis

**092761 ULTIMATE STRENGTH OF COMPOSITE STEEL-CONCRETE STRUCTURE OF SANDWICH**

**SYSTEM.** Recently, various kinds of Arctic offshore structures have been constructed. In designing such structures, designers have to pay particular attention to how to overcome ice loads acting on the structures. The use of the composite steel-concrete structure of a sandwich system appears to be a viable solution for offshore structures in the Arctic. In this paper, theoretical and experimental studies were carried out to study elastic-plastic behavior and ultimate strength composite steel-concrete structure of sandwich system where concrete was placed in between steel plates. The theoretical analysis was performed using the finite element method which was newly developed to incorporate nonlinear characteristics of concrete and interaction between steel and concrete. (Edited author abstract) 2 refs.

**092762 RECTANGULAR HYBRID ELEMENTS FOR THE ANALYSIS OF SANDWICH PLATE STRUCTURES.** The structural behavior of sandwich plate structures are characterized by transverse shear deformations in the core. The assumed stress hybrid finite element technique is particularly suitable for developing sandwich plate bending elements. In the present study, rectangular three-layer sandwich plate elements have been formulated using simple assumed stress functions. Numerical test problems have been solved to examine the convergence property and suitability of these elements. The results are compared with that of a complete quadratic stress mode element and with analytical solutions. Six degrees of freedom per node shell elements are formulated by combining the plate bending elements with membrane elements. A folded plate sandwich panel roof has been analyzed using these elements and the results are compared with the experimental values. The use of simple stress function gives satisfactory results and reduces the size of the matrices to be used, the length of the program, and the computation time for the formulation of element stiffness matrices. **092763 STRUCTURE AND MECHANICS OF THE IRIS LEAF.** The structure of the iris leaf resembles that of a sandwich beam with fiber composite faces separated by a low-density foam core. Such structures have a high specific stiffness because the separation of the faces by the lightweight core increases the moment of inertia of the section with little increase in weight. This paper examines the structure of the leaf of the bearded iris and shows that its flexural stiffness can be explained in terms of the mechanics of sandwich beams. (Author abstract). 17 Refs.

## Structural Design

**092764 USE OF MODAL ENERGY DISTRIBUTION IN THE DESIGN OF HONEYCOMB SANDWICH DECKS.** Through the example of a spacecraft equipment deck, which is generally made of honeycomb sandwich construction, it is shown that modal energy distribution can be used as an effective guideline in improving the deck's frequencies to meet the restrictions imposed upon it. The kinetic energy distribution is employed as a basis for redistributing various packages on the deck. Strain energy distribution is used to identify areas which can be stiffened by bonding 'doubblers' on the face sheets and the doubler thickness is obtained from a sensitivity analysis. (Author abstract) 5 refs.

**092765 INTERACTIVE BUCKLING IN SANDWICH STRUCTURES.** A progressive destabilization in

compressed elastic structures of sandwich construction is identified. The analytical model allows for the independent variation of bending and shear in the section, components that are found in significantly different combinations in the overall and local forms of buckling that make up the interaction. An optimum wavelength for local buckling is identified, which maximizes the interactive effect by bringing the primary and secondary bifurcations together. Examples of sandwich sections drawn from the literature are tested. (Edited author abstract) 25 refs.

## Wave Effects

**092766 LONGITUDINAL IMPACT ON A SANDWICH STRUCTURE BAR (A METHOD OF ESTIMATING THE MODULUS OF RIGIDITY OF THE BOND LAYER).** This paper is concerned with the wave propagation in a sandwich structure bar, the free end of which is struck in the direction of the length by a rigid hammer. The bond layer is subjected to a dynamic shearing strain by the resulting elastic waves, which are generated in both the facing and the core by the longitudinal impact. In taking note of the fact that the magnitudes of the axial strains in the facing and the core as well as the shearing strain in the bond layer depend greatly on the modulus of rigidity of the bond layer, the modulus of rigidity of the bond layer was estimated by comparing the calculated values of the ratio of the axial strain in the core to that in the facing with experimental values. (Edited author abstract) 4 refs. In Japanese.

## Australia

**092767 STRATEGY FOR BLUE MOUNTAINS SEWERAGE SYSTEM UNDER FIRE.** A \$125 million strategy to upgrade the Blue Mountains sewerage system has come under fire from environmentalists who claim that it is based on scientifically unsound studies. The existing facilities are inadequate and rundown despite upgrading work carried out by the Board since 1980, with only 3 of the 12 sewage plants providing tertiary treatment. The Board has decided on an effluent management plan involving the upgrading of 6 of the existing secondary treatment plants to tertiary standard and the addition of disinfection facilities to all plants. The plan also allows for nutrient removal at some plants. However, the Blue Mountains Environmental Council disputes the study, claiming it involved a large degree of questionable extrapolation.

## Management

**092768 MULTICRITERION SELECTION OF WASTEWATER MANAGEMENT ALTERNATIVES.** Multicriterion decision-making (MCDM) techniques are used to analyze a multiobjective wastewater management problem in order to select an appropriate management scheme. A specific case study consisting of 15 alternative management schemes is evaluated with respect to 12 noncommensurable, discrete criteria, using three different MCDM techniques: compromise programming (CP), cooperative game theory (CGT), and ELECTRE I. The case study is the Nogales International Wastewater Management Project, which treats wastewater coming from the twin cities of Nogales, Arizona and Nogales, Sonora, Mexico. Analyses of matrix using the MCDM techniques result in selecting the most satisfying alternative in the case of CP and CGT and narrowing the choice to a few non-dominated alternatives (here, two) in the case of ELECTRE I. (Edited author abstract) 23 refs.

## Crystallization

**092769 SAPPHIRE WHISKERS FROM BOEHMITE GEL SEEDED WITH  $\alpha$ -ALUMINA.** Sapphire whiskers were grown in thin films of boehmite (AlOOH) gel seeded with  $\alpha$ -alumina seeds at temperatures from 900 to 1200°C. The whiskers were 20-60 nm in diameter and had lengths up to 10  $\mu$ m. The diameter was found to increase with temperature. The crystallographic growth direction of the whiskers was at 46° to the co-axis of  $\alpha$ -alumina. The sides of the whiskers were faceted, exposing the pyramidal planes. A special technique used, to prepare the films allowed us to characterize them directly by transmission electron microscopy. Details of the technique are described. (Author abstract) 27 refs.

**092770 SIALON FORMATION BY  $Si^+$  AND  $N_2^+$  ION IMPLANTATION INTO SAPPHIRE.** Single-crystal alumina was implanted firstly with 400 keV  $Si^+$  and subsequently with  $N_2^+$  ions and then annealed at 1673 K in an  $N_2$  atmosphere. The implanted layers were characterized by means of x-ray diffraction, Rutherford backscattering-channeling of 2 mev  $He^+$  ions, and the resonance nuclear reaction  $^{15}N(p,\gamma)^{12}C$ . The annealing of sapphire implanted at ambient temperature resulted in the formation of  $\beta$ -sialon, a solid solution of  $\beta$ -silicon nitride and alumina in the subsurface layer, while implantation at ca. 100 K resulted in the formation of aluminum oxynitride in the surface layer. In the latter case, the implanted silicon atoms were believed not to react with the implanted nitrogen atoms but with the substrate oxygen atoms. These crystalline precipitates were found to have epitaxial relations with the sapphire substrate. (Author abstract) 25 refs.

**092771 SEGREGATION OF MAGNESIUM AND CALCIUM TO THE (101 $\bar{0}$ ) PRISMATIC SURFACE OF MAGNESIUM-IMPLANTED SAPPHIRE.** Auger electron spectroscopy was used to study the segregation of magnesium and calcium to the prismatic plane of sapphire doped with Mg by ion implantation. Segregation behavior depended strongly upon the annealing atmosphere. Air annealing showed Mg segregation to the free surface whereas vacuum annealing resulted in no observable Mg segregation above the detectability limit of our instrument. This is attributed to excessive vaporization of MgO at low oxygen pressures. In the absence of Mg on the surface, strong Ca segregation was observed although the bulk concentration of Ca was below 40 ppm, the total impurity level. The effective heat of segregation of Mg in air was found to be about -1.4 eV in the temperature range 1300° to 1550°C. (Edited author abstract) 24 refs.

**092772 MORPHOLOGY OF SMALL GOLD CRYSTALS FORMED INSIDE SAPPHIRE BY ION IMPLANTATION.** The shape of gold crystals inside sapphire has been studied by transmission electron microscopy. 400 keV gold ions were implanted into sapphire ( $\alpha$ - $Al_2O_3$ ) at a substrate temperature of 1200°C. The gold ions precipitate as small crystals, which have an ordinary f.c.c. structure and dimensions less than 60 nm. The small gold crystals clearly have faceted outlines. The sides of the outlines are parallel to low-index crystal-planes of sapphire. It has therefore been concluded that the shape of the gold crystals is characterized by the foreign crystal (i.e., sapphire), and that the shape should be a tetradecahedron which consists of two {0001} and twelve {21 $\bar{1}$ 3} planes of sapphire. (Author abstract) 6 refs.

## Mechanical Properties

**092773 CHARACTERIZING THE HARDNESS AND MODULUS OF THIN FILMS USING A MECHANICAL PROPERTIES MICROPROBE.** A new ultralow load microindentation has been acquired by the Metals and Ceramics Division of Oak Ridge National Laboratory. The system's spatial resolution and its data acquisition capabilities allow the determination of several mechanical properties from submicrometre volumes of materials, hence the term mechanical properties microprobe. In this paper we demonstrate the ability of such a system to measure the modulus and hardness of an ion-implanted sapphire specimen. The implantation process results in an amorphous surface layer 155 nm thick. The hardness and modulus of the amorphous  $Al_2O_3$  are 10 GPa and 200 GPa respectively. This represents a 60% reduction in hardness and a 50% reduction in modulus compared with the unimplanted material. (Author abstract) 8 refs.

## Melting

**092774 EVAPORATION AND ENERGY TRANSFER FOR A PARTIALLY MOLTEN, LASER-HEATED SAPPHIRE FILAMENT.** Molten regions were formed on 0.025-cm-diameter sapphire filaments that were heated from one side with a continuous-wave  $CO_2$  laser beam in a low-pressure flow reactor. As the laser intensity was increased the liquid/solid interface moved from the laser-heated edge to the opposite edge of the filament, the apparent temperature measured in the molten region with an optical pyrometer increased from 1470  $\pm$  25 to 2040  $\pm$  30 K, and the filament evaporation rate increased by a factor of 1.6. Optical and energy-transfer properties of sapphire and liquid  $Al_2O_3$  were calculated from optical pyrometry, energy-balance measurements, and spectral absorption coefficient data for sapphire. (Edited author abstract) 21 refs.

**092777 FLIGHT OF POLAR BEAR: A SUCCESSFUL SATELLITE PROGRAM GROWS FROM PARTS AND DETAILS.** The Polar BEAR - Polar Beacon Experiment and Auroral Research - satellite had been developed by APL and sponsored by the Defense Nuclear Agency and the U.S. Air Force's Space Division. It carried several experiments designed to improve communications over the earth's polar regions. At high latitudes, solar flares and auroras routinely disrupt the transmissions from a multitude of satellites orbiting overhead for purposes of communications, navigation, and meteorology. They interfere as well with some ground communications and radar signals. The Polar BEAR satellite is expected, during one year of mission time, to provide data that will lead to several new techniques for alleviating the disruptions. The article describes the Polar BEAR experiments, steps in building the satellite, launcher malfunctions and final launching.

**092778 APPLICATION OF ADVANCED TECHNOLOGY TO A PERMANENTLY MANNED SPACE STATION.** Over the last three years, it has been the objective of NASA's Space Station Advanced Development Program (ADP) to provide funds to accelerate promising technologies in generic areas in order to bring them forward as timely application options for the Space Station initial design. New advanced technologies from the NASA funded ADP and the independent research conducted by the United States aerospace industry. Technologies are being tested and matured today in order to provide the Space Station Program Manager the latest options for consideration in the initial design of a Space Station. The ADP covered a span of 14 different disciplines involving some 70 application areas. This article briefly summarizes the most outstanding contributions from selected discipline and presents typical current test data that shows promising applications in four of those areas; namely, Environmental Control and Life Support, Extravehicular Activities, Electrical Power, and Thermal Subsystem Design. **092779 FAMILY OF PERIODIC SOLUTIONS TO THE PROBLEM OF ROTATION OF A SOLID BODY AT A TRIANGULAR LIBRATION POINT IN THE RESTRICTED THREE-BODY PROBLEM.** Families of spatially periodic solutions to the problem of rotation of an axially symmetric solid body and a body with a triaxial central inertia ellipsoid around the libration point  $L_4$  (circular and elliptical) are obtained and studied in the restricted three-body problem. It is assumed that the inertia ellipsoid is nearly spherical. The investigation is conducted using the Poincaré theory of periodic solutions for degenerate Hamiltonian systems. The obtained solutions are numerically investigated. (Author abstract) 6 refs.

Lelyavin, S.N. *Cosmic Res* v 25 n 3 May-Jun 1987 p 276-282.

**092780 EVOLUTION OF THE ROTATION OF A DYNAMICALLY SYMMETRIC GYROSTAT WITH INTERNAL FRICTION.** The author considers the problem of rotation of a dynamically symmetric rigid body with a small free momentum wheel. There is energy dissipation due to viscous friction between the momentum wheel and the body. In the first approximation it is shown by the method of averaging that the problem of rotation

of a rigid body is integrable. An analytical dependence is obtained between the nutation angle and time. An optimal viscosity is found that achieves the quickest decrease of nutation angle. (Author abstract) 9 refs.

Pivovarov, M.L. *Cosmic Res* v 25 n 3 May-Jun 1987 p 282-285.

**092781 UNIAXIAL MAGNETIC ORIENTATION OF ARTIFICIAL SATELLITES.** We consider motion relative to the center of mass of an axisymmetric artificial Earth satellite with a permanent magnet. It is assumed that the mechanical moment acting on the satellite from the geomagnetic field is large, and that the equations of motion contain a large parameter. Using the existence theorems for periodic solutions of ordinary differential equations with a large parameter, we investigate periodic motions of the axis of symmetry of the satellite, in which this axis makes a small angle with the field-strength vector of the geomagnetic field. Such motions can be employed to realize a uniaxial magnetic orientation mode of the satellite. The findings can provide an exhaustive interpretation of the results of numerical calculations. (Author abstract) 3 refs.

Sazonov, V.V. *Mech Solids* v 22 n 2 1987 p 24-29.

**092782 DYNAMICS OF EARTH-ORBITING FLEXIBLE SATELLITES WITH MULTIBODY COMPONENTS.** A novel approach to the dynamics of satellites with flexible multibody components is proposed. The property of invariance under superposed rigid-body motions of geometrically-exact structural theories is employed to refer the dynamics of motion directly to the inertial frame. To avoid numerical ill conditioning, the dynamics of the far field and the near field are treated separately by introducing a rationally-fixed floating frame, which is a parallel translate of the inertial frame. Constraint conditions to determine the orientation of floating frames proposed in the past are thus entirely bypassed. The proposed formulation can accommodate an unrestricted class of maneuvers under the action of follower forces and gravitational force, and is particularly suited for the dynamics of flexible multibody systems undergoing a broad range of deformations. (Author abstract) 26 refs.

**SPACECRAFT DESIGN STUDY.** The Mirrabooka Wide Band Width X-Ray Astronomy satellite is being developed by a consortium comprising the University of Tasmania, ADFA Physics Department and the ANU. The spacecraft is based on the SPARTAN free flying bus developed by NASA. This paper describes a design study being conducted by Hawker de Havilland, in collaboration with the above consortium, which addresses two major tasks: The High Energy Detector; the design integration of the science payload into the SPARTAN bus. The output from the study is the Preliminary Design Review Data Pack, which is an essential step in the NASA review process. (Author abstract)

Raju, J.A.S. *Trans Inst Eng Aust Multi Discip Eng* v GE11 n 1 Apr 1987 p 15-20.

**092785 HIPPARCOS MAIN MISSION ACCURACY SIMULATION.** The Hipparcos satellite is the European Space Agency's (ESA) first mission dedicated to global astrometry. Scheduled for launch by Ariane in 1989, in its 2.5 year nominal lifetime its main mission accuracy goal is to measure the positions and parallaxes of stars brighter than 9th B magnitude with errors of 2 milliarcseconds and proper motions with rms errors of 2 milliarcseconds per year. A study of the main mission accuracy is reported. The work involved early analytical studies followed by the development of simulation programs. Besides allowing an analysis of the effects on the eventual accuracy of satellite design changes, an important side effect was that the programs, by implementing the data reduction on simulated data, enabled us to propose improvements in that reduction and assess their benefits, and to show where no improvement was possible. (Edited author abstract). 2 Refs.

**092787 LYMAN LAUNCHES AUSTRALIA INTO SPACE.** LYMAN is a joint Australian, USA and European scientific satellite which will enable Australian industry to rapidly come up to speed with space technology. This will enable Australian industry to prime contract all future Australian space endeavors. The LYMAN mission will make the first spectroscopic observations of faint sources in the vital Far Ultraviolet band (90-120 nm) and of any sources in the Extreme Ultraviolet band (10-90 nm). The Far Ultraviolet region is important because molecular hydrogen, a major constituent of the interstellar gas, and deuterium, a crucial cosmological probe, can only be studied in detail in this wavelength region. LYMAN will measure simultaneously the amount of cold, warm, and hot plasma in objects ranging from planets to quasars at temperatures ranging from a few thousand to many millions of degrees.

**092788 PERFORMANCE OF A KA-BAND SATELLITE SYSTEM UNDER VARIABLE TRANSMITTED SIGNAL POWER CONDITIONS.** A laboratory hardware-based satellite communication system simulator has been used to measure the effects of transmitted signal power changes on the performance of a Ka-band system. Such power changes can be used to compensate for signal fade due to rain attenuation. This paper presents and discusses the results of these measurements. 6 refs.

**092789 IMPACT OF MODULATION ON OPTIMIZATION OF GROUND TERMINAL AND MOBILE SATELLITE PAYLOAD.** The optimization of the satellite communications payload and ground mobile terminals is applied here to evaluate the impact of the ground modulation technique and required voice quality on the performance and cost of a mobile satellite system. Different analogue and digital modulation techniques are considered, each with different unfaded (C/N<sub>0</sub>) values for the satellite uplink and a given fade margin. Some typical results are given for the ground mobile antenna gain and transmitter amplifier power for different modulations, with the satellite uplink parameters such as the antenna diameter, pointing error and number of beams. They illustrate how such optimization of the total space and ground segments of the Mobile Satellite System is essential to arrive at the total cost given a set of required performance and projected number of users. (Author abstract) 9 refs.

**092790 PROPAGATION EFFECTS ON SATELLITE SYSTEMS AT FREQUENCIES BELOW 10 GHz. A HANDBOOK FOR SATELLITES SYSTEMS DESIGN.** Frequencies below 10 GHz continue to be used for a large fraction of satellite service, and new applications, including mobile satellite service and the global positioning system, use frequencies below 10 GHz. As frequency decreases below 10 GHz, attenuation due to precipitation and gases decreases and ionospheric effects increase. Thus the ionosphere, which can be largely neglected above 10 GHz, receives major attention in this handbook. Although attenuation and depolarization due to rain are less severe below 10 GHz than above, they are nevertheless still important and constitute another major topic. The handbook emphasizes the propagation effects on satellite communications but material that is pertinent to radio navigation and positioning systems and deep-space telecommunications is included as well. (Edited author abstract) Refs.

Flock, Warren L. (Univ of Colorado, Boulder, CO, USA). *NASA Ref Publ* 1108(02) Dec 1987 506p.

**092791 COMMUNICATIONS PAYLOAD CONCEPTS FOR GEOSTATIONARY FACILITIES.** This report summarizes and compares the major results of two NASA sponsored studies that defined potential communications payload concepts to meet the satellite traffic forecast for the turn of the century for the continental United States and Region 2 of the International Telecommunications Union. Future scenarios of aggregations of communications services are presented. Payload concepts are developed and defined in detail for nine of the scenarios. Payload costs and critical technologies per payload are also presented. Finally, the payload concepts are compared and the findings of the reports are discussed. (Edited author abstract) 15 refs.

**092792 SATELLITE GROUND-TERMINAL USER SIMULATION.** Realistic simulation of satellite communication systems and evaluation of satellite networking schemes require emulation of the system's users. A laboratory model of a Ka-band satellite-to-ground time-division multiple-access (SS-TDMA) communica-

tion network, referred to as the System Integration, Test, and Evaluation (SITE) Project, is presently under development at NASA Lewis Research Center. The SITE Project uses special bit-error-rate (BER) test sets to simulate the transmitting and receiving users of a communication network. The bit-error-rate test sets contain circuit boards that can be modified to create a variety of interfaces to satellite system ground terminals. (Author abstract) 2 refs.

**092793 DIGITAL GROUP DEMODULATION SYSTEM FOR MULTIPLE PSK CARRIERS.** A digital group demodulator has been implemented by employing a transmultiplexer (TMUX) that simultaneously translates multiple SCPC carrier signals into the original baseband form. Since the operation rate for the TMUX is determined by the channel spacing and not by the baud rate, an adaptive interpolation function is required for each channel following the TMUX operation, so that the baseband signals can be obtained at the correct decision timing. For this purpose, an adaptive rate conversion (ARC) filter has been introduced. Using the ARC filters, excellent demodulation performance is always obtained for any relation between the channel spacing and the baud rate in an SCPC system. 6 refs.

**092794 USE OF SPREAD-SPECTRUM CODING AS A FADING COUNTERMEASURE AT 20/30 Hz.** The Direct Interestablishment Communications Experiment (DICE) will involve direct business communications (data, voice and video) between geographically separated divisions of a large company by satellite at 30/20 GHz. In order to reduce the effects of fading, the information flow through the system will be reduced in faded conditions to maintain high quality data and voice communications at the expense of some slowing down of the video information. A method of matching variable throughput to the transmission system by means of spread-spectrum techniques is described. This method maintains stable conditions in the satellite and avoids large excursions in link performance, even under severe fading conditions. (Author abstract) 5 refs.

**092798 DYNAMICS AND CONTROL OF THE TETHERED SATELLITE SYSTEM IN THE PRESENCE OF OFFSETS.** A mathematical model for studying the dynamics of the Tethered Satellite System (TSS) is proposed that accounts for a three-dimensional offset of the point of attachment. The system chosen consists of a plate-type space station from which a tether-supported subsatellite is deployed or retrieved. The mass of the tether as well as the rigid body dynamics of the tether, subsatellite and space station are considered. Controllability of the linearized equations is established numerically and the control is achieved through simple velocity feedback using thrusters and momentum wheels. (Author abstract) 13 refs.

**092799 SPACE ATTITUDE DETERMINATION USING A SECOND-ORDER NONLINEAR FILTER.** The stringent attitude determination accuracy and faster slew maneuver requirements demanded by present-day spacecraft control systems motivate the development of recursive nonlinear filters for attitude estimation. This paper presents the second-order filter development for the estimation of attitude quaternion using three-axis gyro and star tracker measurement data. Performance comparisons have been made by computer simulation of system models and filter mechanization. It is shown that the second-order filter consistently performs better than the extended Kalman filter when the performance index of the root sum square estimation error of the quaternion vector is compared. The second-order filter identifies the gyro drift rates faster than the extended Kalman filter. The uniqueness of this algorithm is the online generation of the time-varying process and measurement noise covariance matrices, derived as a function of the process and measurement nonlinearity, respectively. (Author abstract) 35 refs.

## Control Systems

**092800 CCD STAR TRACKER FOR SCIENTIFIC SATELLITES.** A microprocessor controlled star-tracker (STT) using a charge coupled device (CCD) as a detector has been developed for the purpose of being applied to attitude determination and control of a scientific satellite. The STT, with the field of view (FOV) of 8 deg × 6 deg can detect and track a star as dim as 5.7th magnitude with accuracy of better than half an arc-minute. A pair of the STTs are aboard the X-ray astronomy satellite ASTRO-C that was launched on February 5, 1987. In this paper, the STT design, and its sensitivity and accuracy analysis are described. Preliminary in-flight results are also presented. (Author abstract) 8 refs.

## Cryogenic Equipment

**092802 ANALYTICAL STUDY OF He II FLOW CHARACTERISTICS IN THE SHOOT TRANSFER LINE.** Pressure and temperature profiles for He II flow in the transfer line for the Superfluid Helium On-Orbit Transfer (SHOOT) experiment are determined using a finite difference method to solve the one-dimensional two-fluid conservation equations. For practical purposes, forced flow of He II can be treated as a classical turbulent flow. (Edited author abstract) 15 refs.

Lee, J.H. (NASA, Moffett Field, CA, USA); Ng, Y.S.; Brooks, W.F. *Cryogenics* v 28 n 2 Feb 1988 p 81-85.

**092803 DEWAR TO DEWAR MODEL FOR SUPERFLUID HELIUM TRANSFER.** A model has been developed to predict the flow of He II between a source and a receiving dewar. The model uses a finite difference approximation to integrate the describing equations. The transfer path may contain porous plugs or mechanical pumps, heater sections, heat leaks, constrictions due to valves, and bends. These line elements may occur in any order and in any quantity. The line elements are easily reconfigured by changing the input data. (Edited author abstract) 8 refs.

Snyder, H.A. (Univ of Colorado, Boulder, CO, USA). *Cryogenics* v 28 n 2 Feb 1988 p 86-89.

**092804 MECHANICAL PUMPS FOR SUPERFLUID HELIUM TRANSFER IN SPACE.** Two alternate mechanical pump concepts have been identified for the transfer of superfluid helium in space. Both pumps provide flow at sufficient head and have operating characteristics suitable for the Space Infrared Telescope Facility (SIRTF) refill mission. One pump operates at a relatively low speed and utilizes mechanical roller bearings, while the other operates at a higher rotational speed using either electromagnetic or tilting pad gas-dynamic bearings. The use of gas bearings requires transfer of normal helium so that the gas pressure within the pump casing is high enough to operate the bearings. (Edited author abstract) 14 refs.

Izenzon, M.G. (Creare Inc, Hanover, NH, USA); Swift, W.L. *Cryogenics* v 28 n 2 Feb 1988 p 90-95.

**092805 CAVITATION CHARACTERISTICS OF A SMALL CENTRIFUGAL PUMP IN He I AND He II.** The cavitation characteristics of a small pre-induced centrifugal pump operating in He I and He II over the temperature range 1.8-4.2 K are presented. The pump and close-coupled induction motor operate immersed in liquid helium. A six-blade propeller inducer and a three-blade screw inducer were both tested. With this pump configuration using either inducer, there is a tremendous difference between the cavitation characteristics of He I and He II. (Edited author abstract) 6 refs.

Ludtke, P.R. (NBS, Boulder, CO, USA); Daney, D.E. *Cryogenics* v 28 n 2 Feb 1988 p 96-100.

**092806 TURBULENT FLOW PRESSURE DROP IN VARIOUS He II TRANSFER SYSTEM COMPONENTS.** Pressure drop experiments in highly turbulent He II flow were performed in flow loops driven by either a centrifugal pump or a single-stroke bellows pump. Pressure drops in straight tubing, coiled tubing, bellows sections, valves and Venturi flow meters were measured over a range of flow rates and temperatures. Cavitation and, in some cases, metastable superheating were observed in pressure drop measurements with Venturis in both

centrifugal and bellows pump flow circuits. (Edited author abstract) 10 refs.

**092807 SLIP EFFECTS ASSOCIATED WITH KNUDSEN TRANSPORT PHENOMENA IN POROUS MEDIA.** Porous media used in phase separators and thermomechanical pumps have been the subject of characterization efforts based on the Darcy permeability of laminar continuum flow. The present experimental and theoretical studies address questions of slip effects associated with long mean free paths of gas flow at room temperature. Data obtained are in good agreement, within data uncertainty, with a simplified asymptotic Knudsen equation proposed for porous plugs on the basis of Knudsen's classical flow equation for long mean free paths. (Edited author abstract) 14 refs.

**092808 INTEGRATED FOUNTAIN EFFECT PUMP DEVICE FOR FLUID MANAGEMENT AT LOW GRAVITY.** To transfer He II in space, the supply tank must be drained at low gravity. Conventional capillary devices such as the gallery system make use of the capillary retention capability of the screens for fluid management. Liquid helium is collected into gallery channels and then conveyed to the downstream fountain effect pump (FEP) or mechanical pump. In this paper, a new fluid management device is proposed. The screens along the gallery channels are replaced by porous plugs which are responsible for both the fluid retention and pumping (by mechanical effect) of He II. No downstream pump is needed. (Edited author abstract) 5 refs.

**092809 LIQUID/VAPOUR PHASE SEPARATION IN <sup>4</sup>He USING ELECTRIC FIELDS.** In space, a replacement must be found for gravity to physically control and, in certain instances, contain cryogenic liquids. A program has been started at the Jet Propulsion Laboratory to study the use of electric field generated forces to establish the required orienting effects. We present measurements which show that it is possible to apply strong enough electric fields to a liquid/vapor interface of <sup>4</sup>He to obtain an orienting force comparable to gravity. Some advantages of the electric field separator as opposed to passive surface tension devices are identified. (Edited author abstract) 9 refs.

Israelsson, U.E. (JPL, Pasadena, CA, USA); Jackson, H.W.; Petrac, D. *Cryogenics* v 28 n 2 Feb 1988 p 120-125.

**092810 ENCLOSED CAPILLARY DEVICE FOR LOW GRAVITY MANAGEMENT OF He II.** To transfer He II in space, a large tank must be drained at low gravity. This paper describes and analyses an enclosed gallery device designed for collecting and delivering He II to a pump. The device allows most of the liquid to move about in the tank while it maintains a liquid flow to the pump. Only the liquid in the screen-covered gallery channels and in the upper and lower receivers is contained. The device operates by providing surface tension dominated liquid paths from all locations within the tank to the lower receiver, which houses the pump. (Edited author abstract) 13 refs.

**092811 CAVITATION IN FLOWING SUPERFLUID HELIUM.** Flowing superfluid helium cavitates much more readily than normal liquid helium, and there is a marked difference in the cavitation behaviour of the two fluids as the lambda point is traversed. Examples of cavitation in a turbine meter and centrifugal pump are

given together with measurements of the cavitation strength of flowing superfluid helium. We attribute the unusual cavitation behaviour of superfluid helium to its immense thermal conductivity. (Author abstract) 15 refs.

**092813 AI APPLICATIONS FOR THE SPACE STATION.** NASA is currently developing a Space Station for long term usages of space. This Space Station presents NASA with numerous problems which may be best handled by effective use of expert systems. This paper outlines some of the benefits expert systems will provide, some of the issues involved in choosing appropriate applications, and the impact expert systems will have on the design of the Space Station. (Author abstract) 7 refs.

Culbert, Chris (NASA, Houston, TX, USA); Boarnet, Marlon; Savely, Robert T. *Robotics* v 4 n 1 Mar 1988 p 35-40.

**092814 NICHE FOR LIGHTWEIGHT SATELLITES.** Lightweight satellites (lightsats) can be cost effective for missions of 90 days or less. Such low altitude orbits increase ground resolution and reduce telemetry power and antenna size. Sounding rockets, rather than scaled-down satellites, are the best model for lightsat design, fabrication, and operation. Economical ways to launch lightweight payloads are critical to the future of lightsats. Making available several options depends on the establishment of standards for the vehicle/payload interface. Several proposals for small launch vehicles have appeared, but right now progress is impeded because launch-vehicle designers do not know which satellite their vehicle will handle, and satellite designers do not know what accommodations to make for the launch vehicle.

**092817 DEVELOPMENT OF THE RADARSAT SAR ANTENNA.** The Canadian RADARSAT Remote Sensing Satellite will employ a Synthetic Aperture Radar (SAR) as the primary instrument. This SAR instrument will be able to alter its beam-pointing angle to anywhere within a 500 km Earth ground track, with either a wide or narrow swath, at ground incidence angles from 20 to 49 degrees. This ability to alter the ground track is unique, and neither existing nor planned remote sensing satellites can provide such complete ground access. A major factor that allows this flexibility is the electronically steerable SAR antenna. The SAR antenna represents the single most important technology development for the RADARSAT program, being critical to the performance of the switchable radar. The baseline design is a 15 m by 1.5 m slotted waveguide planar array that extends from a folded launch configuration, which requires the use of RF as well as mechanical joints in the hardware implementation. The ability to reconfigure the ground coverage is provided by electronic beam switching in the SAR Antenna using ferrite variable phase shifters in the elevation (across track) beam forming network. In order to fulfil the performance specifications of the radar system, the SAR antenna must meet stringent electrical and mechanical requirements. Accordingly, an electrical breadboard model was fabricated and tested in order to confirm the viability of the baseline concept. (Edited author abstract) 3 refs.

## Fuel Cells

**092818 REGENERATIVE FUEL CELL STUDY FOR SATELLITES IN GEO ORBIT.** This paper summarizes the results of a 12-month study to identify high-performance regenerative hydrogen-oxygen fuel cell concepts for geosynchronous satellite application. Emphasis was placed on concepts with the potential for high energy density (watt-hours/lb) and passive means for water and heat management to maximize system reliability. Both polymer membrane and alkaline electrolyte fuel cells were considered, with emphasis on the alkaline cell because of its high performance, advanced state of development and proven ability to operate in a launch and space environment. Three alkaline system concepts were studied. (Edited author abstract).

**092819 GLOBAL TRACKING NETWORKS FOR CRUSTAL DYNAMICS.** Highly accurate Satellite Laser Ranging (SLR) and Very-Long-Baseline Interferometry

(VLBI) have been implemented by the NASA Crustal Dynamics Project and many cooperating groups in many countries to form global SLR and VLBI networks for geodetic measurements of global plate motion, plate deformation, regional deformations in areas of high earthquake activity, and accurate measurements of the Earth's polar motion and changes in rotation rate. These systems are measuring vector baselines between stations to an accuracy of 2-5 cm. New improvements being implemented will improve the accuracy to about 1 cm. (Author abstract) 10 refs.

Coates, Robert J. (Goddard Space Flight Cent, Greenbelt, MD, USA). *Acta Astronaut* v 17 n 1 Jan 1988 p 53-60.

**092820 SENSING BY SATELLITE.** Among the many satellites orbiting the earth several times each day are Landsat and SPOT, commercial ventures that collect image data to order for paying customers. These images are rapidly changing the way civil engineers look at the world. Equally impressive is the growing availability of software for small computers that allows sophisticated processing of the satellite data. Such processing can reveal a wealth of data about the landscape. Land usage, the geologic and hydrologic character of an area, and the extent of events such as floods, landslides, crop diseases and snowfall are just a few of the applications. This paper reviews the satellite imagery separation for different surveying tasks.

**092821 LAUNCH AND OBSERVATION PROGRAM OF THE EXPERIMENTAL GEODETIC SATELLITE OF JAPAN.** The functions, specifications, and observation equipment of Japan's Experimental Geodetic Satellite (EGS) are described along with the nature of observations made since its August, 1986 launch. The functions of the EGS are 1) to reflect input laser light back toward the ground for precise ranging and 2) to reflect solar light to determine the direction to the satellite from an observation site. The satellite is a hollow sphere, 2.15 m in diameter, and weighs 685 kg. The surface is covered with corner cube reflectors and separate solar light reflectors. The launch orbit is circular with an inclination of 50° and altitude of 1500 km. Tracking observation was started by Japanese and cooperative international organizations using satellite laser ranging (SLR) systems and optical cameras just after the launch. The range precision given by some NASA SLR systems reached 1 cm. Observations in isolated islands also will be made using a transportable laser ranging station with a range accuracy of 5 cm. The Hydrographic Department of Japan will obtain and use positioning data in construction of a marine geodetic control network. 11 refs.

## Magnetic Field Effects

**092825 INFLUENCE OF GEOMAGNETIC FIELD INHOMOGENEITIES ON THE DYNAMICS OF A SCREENED SATELLITE.** The influence of inhomogeneities of the Earth's magnetic field is studied as it affects the stability of the relative equilibrium positions of an Earth satellite which has a cylindrical screen for electrostatic protection and moves on a circular equatorial orbit. The necessary and sufficient stability conditions are derived. The regions of admissible values of satellite parameters are constructed. The type and degree of influence are described for each of the components of the principal moment of Lorentz forces, introduced by the inclusion of the geomagnetic field inhomogeneity in the screen volume as it influences the dimensions of the regions and the vibration frequencies of the satellite. (Author abstract) 8 refs.

## Marketing

**092827 DO'S AND DON'TS OF SATELLITE PROCUREMENT.** 12 guidelines are suggested which, coupled with common sense and flexibility, can produce significant savings and advantages for a procuring agency compared to a fixed and intransigent approach. It is argued that a flexible approach is more rewarding than a rigid tender containing strict 'design specifications', and difficult stiff penalties. Cooperative efforts to achieve economies also help the manufacturer understand the buyer's particular

constraints and lead to better working relationships. (Edited author abstract). 1 ref.

**092828 STANDARD-C AND POSITIONING.** The International Maritime Satellite Organization (INMARSAT) began operations in February 1982. It took over the MARISAT system. In the navigation and positioning field INMARSAT will demonstrate the capability and benefits of relaying position information through the INMARSAT system for both the maritime and aeronautical communities. As a natural extension, a series of ranging tests and demonstrations will be conducted and a feasibility study related to the provision of a passive navigation capability and an integrity channel for other navigation systems will be undertaken.

**092829 INTEGRATION OF GPS AND STRAPDOWN INERTIAL SUBSYSTEMS INTO A SINGLE UNIT.** Direct design at the outset of a tightly integrated GPS and strapdown INS allows optimization of both for performance and cost. Using this approach, a properly designed slow-sequencing, single-channel receiver, married to a low-cost strapdown inertial unit, provides satellite tracking during 10-g acceleration, very high jamming suppression, improved strapdown inertial outputs, and improved GPS navigation accuracy. Packaging this 'GPS/I' in a single unit reduces software and hardware redundancies, and results in a very low-cost design. (Edited author abstract) 9 refs.

**092830 COMNAV-COMMUNICATION/NAVIGATION FOR GLOBAL APPLICATIONS.** A short description of existing and proposed satellite navigation systems is given, followed by a discussion of requirements and chances for the realization of such a worldwide system for civil application. To avoid the extremely high cost of a dedicated satellite system for navigation tasks only, a different and less expensive approach is presented in this paper. It combines communication with navigation by utilizing conventional geostationary and additional high eccentric (LOOPUS) orbit spacecraft. Special attention is given to the orbital configuration of COMNAV, especially the LOOPUS orbit. It can be shown that such an integrated system can fulfill all user demands while simultaneously reducing establishment cost and increasing the chances of early introduction into service. **092831 GRAPHIC DEPICTION OF DYNAMIC SATELLITE CONSTELLATION ACCURACY/COVERAGE OVER TIME.** The Global Positioning System (NAVSTAR/GPS) should reach full 3D capability in mid-1990. The constellation is expected to consist of 18 basic satellites and three active spares deployed in six orbital planes. The proposed constellation yields occasional geometric configurations that result in poor navigation solutions, of importance to both the civilian and military aircraft communities. Analyses were undertaken to determine if placing the three active spares in an equatorial orbit at the same altitude as the other satellites

would improve the situation. The analyses demonstrate the equatorial concept of sparing provides certain advantages over the 6 orbit, 21 satellite constellation currently proposed, provided certain new constraints are acceptable and the true mask angle is within the expected range. (Edited author abstract) 6 refs.

**092832 OPTIMAL LOCATIONS OF PSEUDOLITES FOR DIFFERENTIAL GPS.** Because of the announced DOD policy to degrade GPS accuracy, Differential GPS has assumed increasing importance. Furthermore, the delay in operational deployment of the NAVSTAR satellites has focused increased attention on the use of pseudo-satellites (pseudolites or PLs) to enhance accuracy and provide earlier operational capability. This paper examines the following problem: What is the best location for a PL when one considers the worst possible satellite outage in twenty-four hours? What is the resulting worst case GDOP (Geometric Dilution of Precision)? Both single and dual PL systems are considered, and the results are extrapolated to expected user receiver performance (horizontal and vertical errors). The results indicate that a dual PL system will outperform the satellite-only GPS system, even with a worst case satellite outage. In addition, there should be negligible degradation during periods when the military intentionally reduces ephemeris or clock accuracy. Furthermore, the accuracy of such a system would provide aircraft positioning very close to Category I FAA landing requirements. (Edited author abstract) 15 refs.

**092833 DIFFSTAR: A CONCEPT FOR DIFFERENTIAL GPS IN NORTHERN NORWAY.** During the Fall of 1984 A/S Kongsberg Vaapenfabrikk (Kongsberg) started a project to investigate the improvement which could be obtained if GPS was used in differential mode. One of the main elements of the project was a field test employing two GPS receivers collecting data for post-processing. Based upon the results of the feasibility study, a project was started. The aim was to develop a real time differential GPS system by the Spring of 1986, based on a GPS receiver developed by Kongsberg. The carrier of the differential message is the Consol navigation system. Consol has been closed down as a navigation system in Northern Norway. The frequency (320 KHz) and the transmitter will be used for the differential GPS-system. The Consol system has a range capability of approximately 1000 km from the reference station. (Edited author abstract)

**092834 MEASUREMENT ERRORS IN GPS OBSERVABLES.** Airborne users of GPS may benefit from differential (relative) navigation to the extent that the errors in their measurements of pseudorange and/or delta range to each satellite are correlated with observation errors for the same satellite signals received at a reference site. This paper describes some results of an experiment to characterize the measurement errors of one airborne GPS user equipment. The results suggest that pseudorange errors are dominated by slowly varying systematic processes that are likely to be highly correlated from user to user, whereas delta-range errors appear to be zero-mean processes that are dominated by user generated noises, especially clock jitter and tracking errors. (Author abstract) 3 refs.

**092835 GPS FAILURE DETECTION BY AUTONOMOUS MEANS WITHIN THE COCKPIT.** In civil

aviation, it is desirable to be able to detect navigation system failures quickly and alert the pilot and crew accordingly. Also, while not absolutely necessary, it certainly would be simpler in the GPS case if the detection could be done autonomously within the cockpit rather than via a communication link with a network of monitoring stations on the ground. The scheme used for failure detection in this investigation is the Magill adaptive filter, which is also known as the Multiple Model Estimation Algorithm (MMEA) in control theory. Preliminary results indicate that soft ramp-type satellite clock failures can be detected and identified in a relatively short time for the low dynamic environment that might be encountered in the high-altitude enroute situation. Failure detection is more difficult in the low-altitude nonprecision approach scenario, but preliminary results indicate that this can also be done. (Edited author abstract) 10 refs.

**092836 SELF-CONTAINED GPS INTEGRITY CHECK USING MAXIMUM SOLUTION SEPARATION.** Previous approaches to the self-contained GPS (Global Positioning System) integrity problem have been in a hypothesis testing setting where the two hypotheses are: (1) a single satellite has failed, or (2) there is no failure. In this setting, selective availability is the major source of noise that impedes the detection scheme's ability to detect failures and, at the same time, have a low false alarm rate. This paper poses the problem in a different setting where the basic questions posed are: (1) is the radial position error less than some present bound? or (2) is it greater than that bound? This is a more fundamental approach, because the pilot does not really care where the error comes from; rather, he is only concerned that the radial position error does not exceed a certain specified level. Results of Monte Carlo simulations using a 24-satellite constellation and maximum separation of redundant solutions as the test statistic are presented. These results indicate that this scheme could provide radial error protection of about 250 m with acceptably low alarm and miss rates. (Edited author abstract) 8 refs.

**092838 GLOBAL POSITIONING SYSTEM (GPS) AUTONOMOUS USER SYSTEM.** A GPS autonomous navigation system will be operational with the GPS Block IIR satellites in the first decade of the twenty-first century. This system will provide the user with full navigation accuracy for 180 days even if the GPS Operational Control Segment (OCS) is inoperable. Until such a system is operational, GPS navigation accuracy depends on a functioning OCS. If the OCS fails, the navigation accuracy degrades rapidly. To provide interim full-system accuracy in the event of loss of the OCS, an Autonomous User System (AUS), requiring user segment modification only, has been designed, implemented, and field tested. In this paper, the AUS is described, and test results are presented. These results indicate that, in the 180-day period, the autonomous user can achieve a navigation accuracy of the

same order of magnitude as is obtained when the OCS is functioning. The AUS concepts are also applicable to other navigation systems. (Author abstract). 8 Refs.

**092839 CHOOSING THE BEST SOLUTION TO THE GPS INTEGRITY AND COVERAGE ISSUES.** The FAA has stated that use of the GPS as a sole means civil aviation radionavigation system requires that a user be quickly notified of out-of-tolerance conditions (the 'integrity' issue), and that the system provide adequate coverage even with satellite failures (the 'coverage' issue). These FAA concerns have prompted numerous research studies aimed at warning GPS users of anomalous conditions and improving satellite coverage. Approaches to the integrity issue include implementation of ground-based monitor stations to evaluate GPS signals (combined with various techniques for disseminating warnings to users), and processing of redundant data within the GPS receiver to detect anomalies and autonomously provide warning. Approaches to the coverage issue include expansion of the Department of Defense (DoD) constellation to 24 semisynchronous satellites, augmentation by dedicated geosynchronous GPS satellites, and addition of a civil GPS payload on existing geosynchronous civil weather satellites. (Edited author abstract). 25 Refs.

Damiani, T.R. (Rockwell Int, Seal Beach, CA, USA); Hemesath, N.B. *Navigation* v 35 n 2 Summer 1988 p 217-237.

**092840 NEW CONCEPT FOR INDEPENDENT % > GPS% INTEGRITY MONITORING.** Monitoring of the GPS signals-in-space status for integrity, with a fast response time, is essential if the system is to be used by civil aviation for nonprecision approach guidance. One alternative for providing such a monitoring function is to employ an independent monitoring system with a few ground-based signal monitors to cover a region and a satellite-based integrity broadcast channel to provide real-time GPS signal status. This paper introduces a new decision concept for accepting or rejecting a GPS signal for navigation in the independent monitoring system. Performance of the new concept is evaluated in terms of the probability of alarms against position error protection level, which are two important parameters for any integrity method. (Author abstract). 9 Refs.

Lee, Young C. (MITRE Corp, McLean, VA, USA). *Navigation* v 35 n 2 Summer 1988 p 238-254.

**092841 AUTONOMOUS GPS INTEGRITY MONITORING USING THE PSEUDORANGE RESIDUAL.** The use of GPS for navigation-critical applications such as aircraft nonprecision approach or harbor and river crossings requires the navigation data to be both extremely accurate and extremely reliable. This paper describes a method for autonomous GPS satellite failure detection and isolation (D/I). The test statistic for the D/I algorithm is the range residual parameter for six or more satellites in view. Based on experiments conducted at Stanford, nominal carrier-aided pseudorange measurement errors are modeled as Gaussian random variables with mean in the range from -5 m to +5 m and standard deviation of 0.4 m. The theoretical statistical distribution of the range residual is given. Monte Carlo simulations present results of applying the algorithm to measurement sets containing a biased measurement. With a 100 m biased measurement present, successful detection is achieved 99.9 percent of the time, and successful D/I is achieved 72.2 percent of the time. (Edited author abstract). 20 Refs.

**092842 HIGH-ACCURACY KINEMATIC POSITIONING BY GPS-INS.** Recent results achieved with relative GPS positioning techniques indicate that accu-

cies at the meter level are possible in land vehicle mode if the cycle slip problem can be minimized. One of the possible solutions to the problem is the integration of GPS and inertial data. Results from inertial surveys show that, with regular, accurate coordinate or range updates, an INS will give velocity estimates at the cm/s level. By integrating differential GPS measurements with an INS, the effect of cycle slips over short intervals may be eliminated from the positioning results. A Kalman filter-smoother to handle this problem has been developed. It integrates differential range and phase measurements with data from an inertial navigation system. The optimal backward smoother improves the filter estimates for periods of poor geometry and multiple cycle slips. Results of the test show that sub-meter kinematic positioning accuracies and cm/s velocity accuracies are achievable with an integrated GPS-INS. (Edited author abstract). 13 Refs.

**092843 INDEPENDENT GROUND MONITOR COVERAGE OF GPS SATELLITES.** The Federal Aviation Administration plans to monitor independently signals in space from the Global Positioning System (GPS) for the purpose of providing immediate awareness to civil aviation users of the operational status of GPS when it is used in the National Airspace System. The operational status will be disseminated to air traffic control and will possibly be broadcast from ground monitoring stations to GPS aviation users via a dedicated integrity channel. An algorithm is described that measures the coverage of a configuration of ground monitoring station locations, and it is applied to several different configurations of ground monitoring stations to compare the coverage provided. Also included are the resulting ground monitoring station configurations that give the best coverage of GPS signals for several specific geographical areas, the conterminous United States (CONUS), Canada, and Alaska. 5 refs.

**092844 NAVSAT: A GLOBAL SATELLITE BASED NAVIGATION SYSTEM.** A description is given of the NAVSAT concept, developed by the European Space Agency to fulfill the civilian user requirements for a better navigation capability and mobile communication needs in the future. In selecting the NAVSAT architecture, special care has been devoted to different satellite constellation alternatives in order to identify the most promising solution in terms of navigation performance and system cost. The present NAVSAT baseline, while offering precise navigation performance comparable or better than the Global Positioning System (GPS), cuts significantly the overall cost of a satellite navigation system. The particular constellation selected is also easing the set up of the integrated navigation-communication-search-and-rescue service.

## Observatories

**092848 EARTH OBSERVATION FROM THE SPACE STATION.** The Polar Platform as an element of the international Space Station programme offers real opportunities to provide remotely sensed data in a routine way to meet the operational needs of the Earth Observation science and applications community. The paper identifies application priorities for the Polar Platform and the associated measurement requirements. The importance of data handling is stressed and proposals made to involve user based data centres in the Polar Platform ground segment. An adequately funded national Polar Platform Preparatory Programme is recommended to develop applications and to prepare the user community. Suggestions are made for a UK sensor development programme that complements instruments provided through ESA. (Edited author abstract)

**092849 IRAS KNOWN ASTEROID PREDICTION AND ASSOCIATION.** IRAS (Infrared Astronomical Satellite) was launched on January 25, 1983, with the primary purpose of performing a survey of the entire celestial sphere in four infrared wavelength bands. To strive for completeness and reliability for the fixed point sources, 95% of the sky was covered with at least four scans of the telescope field of view. This type of coverage detects moving objects, such as asteroids, at more than one location. To identify each moving object, all of the detections from a single source must be extracted and then linked together. This paper describes the techniques and procedures used to obtain data concerning the known asteroids from the set of observations produced by the IRAS satellite. (Author abstract) 7 refs.

**092850 PROMISE OF THE HUBBLE SPACE TELESCOPE.** No other NASA scientific spacecraft has attracted so much attention during its development than the Hubble Space Telescope (HST). This is in large part due to the enormity of the technical challenges but also due to the series of delays generated both within the program and by the hiatus in flights of the Space Shuttle. This attention should not detract from the paramount

scientific role that we expect the HST to play. It will present a leap in orders of magnitude in observational capability in optical astronomy, opening up new areas of investigation. Experience in its operation will also determine the wisdom of the 'great observatories' approach that NASA has assumed for the major astronomy and astrophysics disciplines. (Author abstract) 14 refs.

O'Dell, C.R. (Rice Univ, Houston, TX, USA). *J Br Interplanet Soc* v 41 n 1-2 Jan-Feb 1988 35-40.

**092851 RADARSAT - CANADA'S FIRST EARTH OBSERVATION SATELLITE.** RADARSAT is a Canadian-led co-operative program with the UK and USA to launch and operate a remote sensing satellite with a Synthetic Aperture Radar (SAR) as the principal sensor. Other instruments may include a Radar Altimeter (RA) and an Along-Track Scanning Radiometer (ASTR). The spacecraft is scheduled for launch into a sun-synchronous polar orbit in 1994 on an expendable launch vehicle for a five-year mission. The right-looking SAR, with the unique ability to shape and steer the radar beam over an 800 km accessibility swath, will provide daily Arctic coverage, three-day coverage of the Canadian land mass, and 16-day coverage of the globe. The RA is expected to have a 25 km swath along the spacecraft nadir track, and will also provide global coverage every 16 days. The objective of the RADARSAT program is to generate data of both applications and research value related to global ice, oceans, renewable resources and nonrenewable resources. The spacecraft platform will be a low-earth orbit derivative from the ESA Olympus geostationary orbit spacecraft. The expendable launch vehicle will probably be a Titan IV. The spacecraft will have an ability to store the instrument data which can later be transmitted to an appropriate data acquisition station, thus ensuring global coverage by the sensor complement. (Edited author abstract) 15 refs.

**092852 GROUND SYSTEM FOR THE XUV WIDE FIELD CAMERA ON ROSAT.** In addition to its large X-ray telescope, the W. German ROSAT satellite will carry an XUV telescope (the Wide Field Camera, WFC) provided by the United Kingdom, and covering the wavelength range from 60 to about 600 Å. The primary scientific objective of the mission is to perform all-sky surveys in the X-ray (6-80 Å) and XUV (60-200 Å) wavebands. The subsequent pointing phase will be used for detailed studies of selected sources. I describe the Ground System which will be responsible for WFC mission operations and data handling, and discuss some of the scientific results expected from the instrument. (Author abstract). 10 Refs.

Pye, J.P. (Leicester Univ, Leicester, Engl). *J Br Interplanet Soc* v 41 n 8 Aug 1988 p 337-343.

**092853 ROSAT WIDE FIELD CAMERA XUV TELESCOPE.** If all goes to plan early 1990 will see NASA launch the West German X-ray astronomy satellite ROSAT. On-board will be the main X-ray telescope designed to view the energy range 0.15 to 2.0 KeV while alongside will be the XUV Wide Field Camera built by the United Kingdom to cover the lower energy band 0.062 to 2.21 KeV. The prime objective of the mission is to perform an all-sky survey of soft X-ray sources with a sensitivity much better than has previously been possible and an energy band extending to the extreme ultraviolet, a region of the electromagnetic spectrum which has so far remained largely unexplored. (Author abstract). 21 Refs.

**092854 QUICK-LOOK FACILITY FOR THE XUV WIDE FIELD CAMERA ON ROSAT.** The British XUV Wide Field Camera (WFC) will form part of the ROSAT X-ray astronomy satellite due to be launched in 1990. Since commanding of the satellite and data reception will

take place in Germany, project staff in the UK will not have immediate access to telemetry data and thus will be unable to carry out near real-time monitoring of the functioning of the instrument and the quality of the scientific data returned. This will be the primary responsibility of the WFC Quick-Look Facility (OLF). Attached to the ROSAT Science Data Centre (RSDC) at the Max Planck Institute for Extraterrestrial Physics (MPE) near Munich, the OLF will serve as the front-end of the WFC ground system. The planned tasks and operation of the OLF and its interface with the UK and German ground systems are outlined. (Author abstract). 2 Refs.

**092857 PRELIMINARY ORBIT DETERMINATION USING SATELLITE-TO-SATELLITE LIMITED RANGE AND RANGE-RATE DATA.** A method is presented for the problem of preliminary orbit determination by use of limited range and/or range-rate data with random initial guesses. This method, based on observation function minimization techniques, is essentially a deterministic process. The problem considered consists of an unknown geocentric satellite observed by either one or two tracking satellites using minimum measurement data sets for the determination of the unknown satellite's orbital elements. Additional data, in excess of the minimum data, are used to identify spurious solutions. (Edited author abstract) 8 refs.

807-811.

**092858 MACRO-MEASUREMENTS CONCEPT: A TOOL FOR SPECIFICATION OF RADIO-LOCALIZATION SYSTEMS.** Within the scope of problems concerning orbit computation, our study is based on information obtained from the set of measurements performed during one satellite pass within visibility of a tracking station. At best, this information is restricted to a number of geometrical components which are studied and interpreted. It is the aggregate of the set of geometrical components obtained during the set of passes which allow orbit computation to be performed. The quality of this information is then examined, i.e. the precision of geometric components obtained and factors liable to have a negative effect. Signature errors of elementary measurements performed during each pass and which may seriously impair orbit computation are finally considered. (Edited author abstract)

**092859 ORBIT AND ATTITUDE CONTROL OF A GEOSTATIONARY INERTIALLY ORIENTED LARGE FLEXIBLE PLATE-LIKE SPACECRAFT.** The paper presents design of a near optimal orbit and attitude control system for a very large flexible rectangular flat plate-like spacecraft in geostationary orbit, with its normal kept in the orbital plane in an inertial orientation. First, assuming the plate to be rigid, an optimal control system is designed. Two control systems are needed: one to balance the gravity gradient torque and the other to control the plate's orbit and attitude against disturbances. The interaction of the structural dynamics with control system is investigated next. It is shown that the structural dynamics destabilizes the control system. The control design is modified to reduce the interactions, by including just a couple of flexural modes into the control logic and by optimally locating the thrusters a little away from the corners. An approach to find an optimal location of actuators and a concept of 'associated modes' are also proposed. (Edited author abstract) 14 refs.

**092860 PREFERRED COORDINATE SYSTEM AND THE ASSOCIATED ORIENTATION REPRESENTATION IN ATTITUDE DYNAMICS.** Librational equations of motion when expressed in terms of local coordinates presented in this paper yield a set of rational differential equations devoid of planes of singularity. For a specified level of accuracy in numerical integration, a rational set requires less CPU time than an equivalent transcendental set. To interpret the results of the integration, the time evolution of orientation is presented as a curve in the three dimensional topological space RP3. The above new local coordinates is an example of a globally defined nonsingular rational parametrization of space of rotations suitable for problems of dynamics involving general rotations. (Author abstract) 8 refs.

Marandi, S.R. (Univ of British Columbia, Vancouver, BC, Can); Modi, V.J. *Acta Astronaut* v 15 n 11 Nov 1987 p 833-843.

**092861 LAUNCH VEHICLE TRAJECTORY OPTIMIZATION.** A launch vehicle trajectory optimization software is developed using diagonalized multiplier approach. A new modification, in which the Kuhn-Tucker vector norm is minimized along the multiplier update direction, avoids violent initial multiplier corrections. The optimality of the solutions is established, and robustness of the package demonstrated. This package is presently employed as a standard tool for mission design studies at the Indian Space Research Organisation. 12 refs.

Adimurthy, V. *Acta Astronaut* v 15 n 11 Nov 1987 p 845-850.

**092862 SEMIANALYTIC SATELLITE THEORY FOR ORBITAL DECAY PREDICTIONS.** An extended form of the method of averaging, which uses the true anomaly as the fast variable, is applied to the long-term prediction of near-Earth orbits perturbed by an oblate geopotential and atmospheric drag. This paper proposes the analytical averaging of the drag perturbation as an efficient alternative to the usual numerical procedure. Similarly, an analytic version of a well-known numerical atmospheric model provides accurate reference density data on a global scale. A local representation of this model generates the density profile along the orbit in a form suitable for analytical averaging. The design of the local density model includes a theoretical determination of its order of approximation, similar to the order of quadrature in numerical averaging. The problem of accurately modeling the density profile along a highly-eccentric orbit is successfully resolved by an analytic technique that leads to a substantial reduction in the number of costly density evaluations. The analytics are completely independent of the global density model, they allow the inclusion of the dominant gravity-drag coupling effects, and they resolve earlier convergence difficulties caused by series expansions in powers of the orbital eccentricity. (Edited author abstract) 60 refs.

**092863 EVOLUTION OF THE ORBITS OF DISANTARTIFICIAL SATELLITES.** The main features of the evolution of the orbits of artificial earth satellites with semimajor axes from 100,000 to 200,000 km are investigated over time intervals on the order of 5-10 years. A variant of the numerical analytical method published previously by the author has been used for the investigation. The results obtained by this method adapted to the conditions of the satellite problem are compared with the result of the numerical integration of the rigorous equations of motion of artificial earth satellites with allowance for lunar and solar perturbations. The ranges of change of the eccentricities and inclinations for almost circular initial orbits of artificial earth satellites with semimajor axes of 125,000 and 160,000 km have been determined over an interval of 10 years. (Author abstract) 8 refs.

**092864 TWO-DIMENSIONAL PERIODIC MOTION OF A SATELLITE RELATIVE TO ITS CENTER OF MASS NEAR A COLLINEAR LIBRATION POINT.** Periodic motions of a satellite relative to its center of mass are studied in the vicinity of point  $L_2$  of a periodic circular orbit in the restricted three-body problem. The satellite is represented as a solid body with an arbitrary central inertial ellipsoid. The existence and stability of periodic motions generated by two-dimensional rotation and oscillation of arbitrary amplitude are considered. (Author abstract) 7 refs.

**092865 CONTRACTION OF SATELLITE ORBITS UNDER THE INFLUENCE OF AIR DRAG. VIII. ORBITAL LIFETIME IN AN OBLATE ATMOSPHERE, WHEN PERIGEE DISTANCE IS PERTURBED BY ODD ZONAL HARMONICS IN THE GEOPOTENTIAL.** This paper is devoted to developing the necessary orbital theory for predicting the lifetimes of satellites moving in an oblate atmosphere and subjected to the perturbations due to odd zonal harmonics in the geopotential. The effects of odd zonal harmonics and atmospheric oblateness are expressed as multiplying factors,  $F(\alpha_z)$  and  $F(\alpha_o)$ , to be applied to the lifetime predictions calculated in the absence of the perturbations. The results are valid for the great majority of orbits about the Earth, and in particular for all orbital eccentricities between 0 and 1; but the limits set for the controlling parameters exclude near-polar orbits with perigee heights lower than about 180 km, and orbits having inclinations within a narrow band centered on 63.4°. **092866 PREDICTED SOLAR CYCLE TWENTY-TWO 10.7 cm FLUX AND SATELLITE ORBIT DECAY.** This study develops an empirical model of the 10.7 cm solar flux ( $F_{10.7}$ ) through solar cycle twenty-two as it relates to the problem of a low-Earth orbiting satellite and its orbit decay. A comparison between the predicted orbit decay using the model and the first thirty-seven months of actual altitude of the Solar Mesosphere Explorer (SME) satellite is conducted. The predicted orbit semimajor axis is solved as a function of atmospheric density using a modified Jacchia 1971 atmospheric model (J71). J71 densities vary based on the empirically modeled  $F_{10.7}$  of solar cycle twenty-two. The derivation of the orbit radius,  $r$ , related to atmospheric mass density,  $\rho$ , is outlined, as are the simplifications made in this study for atmospheric density modeling. The  $F_{10.7}$  model for solar cycle twenty-two is then detailed with a comparison to one other model. Finally, the results of the predicted SME orbit decay are evaluated against the actual orbit decay. (Author abstract) 27 refs.

**092867 ON THE COLLISION HAZARD OF COLLOCATED GEOSTATIONARY SATELLITES.** The collision hazard of 2 collocated geostationary satellites within a  $\pm 0.1^\circ$  tolerance window is investigated by computer simulation of the controlled motion including the error effects of modeling, orbit determination and maneuver execution. Several modifications of the basic station-keeping strategy are introduced in order to separate the two satellites, even in the presence of errors. The latter are simulated by a multivariate normal random generator and superimposed on the controlled motion. Roughly 500 years of station-keeping are simulated for each separation policy. The statistical evaluation indicates that identical control strategies for both satellites lead to a high collision risk, and only some of the tested separation policies reduce the hazard to an acceptable level at the cost of a small increase in fuel consumption. **092868 ECONOMICAL SEMI-ANALYTICAL ORBIT THEORY FOR MICRO-COMPUTER APPLICATIONS.** An economical algorithm is presented for predicting the position of a satellite perturbed by drag and zonal harmonics  $J_2$  through  $J_4$ . Simplicity being of the essence, drag is modeled as a secular decay rate in the semi-major axis (retarded motion); with the zonal perturbations modeled from a modified version of the Brouwers formulas. The algorithm is developed as: an alternative on-board orbit predictor; a back up propagator requiring low energy consumption; or a ground based propagator for microcomputer applications. (e.g., at the foot of an antenna). An  $O(J_2)$  secular retarded state partial matrix (matrizant) is also given to employ with state estimation. The theory has been implemented in BASIC on a inexpensive microcomputer, the program occupying under 8K bytes of memory. Simulated trajectory data and real tracking data are employed to illustrate the theory's ability to accurately accommodate oblateness and drag effects. (Author abstract) 13 refs.

**092869 MOTIONS OF A SATELLITE THAT ARE ASYMPTOTIC TO ITS ECCENTRICITY OSCILLATIONS.** We consider plane motions of a rigid-body satellite relative to the center of mass in a central Newtonian gravitational field in an elliptic orbit. We

demonstrate that existence of motions that are asymptotic to stable (in linear approximation) periodic oscillations of the satellite in a low-eccentricity orbit. Our investigation is based on a general analysis of the problem of asymptotic solutions of a conical system of second-order differential equations, whose Hamiltonian is periodic relative to the independent variable. 17 refs.

**092870 GEOSTATIONARY TETHER SATELLITE SYSTEM AND ITS APPLICATION TO COMMUNICATION SYSTEMS.** The geostationary tether satellite system expands the geostationary orbit resource from a one-dimensional arc into a two-dimensional disk. The tethered satellites, each several thousand kilometers apart and aligned along the local vertical, are stabilized at the altitude of the geosynchronous orbital speed. When this system is applied to communications systems, it is estimated that the number of satellites can be increased as much as thirteenfold and the communication capacity can be increased more than seventeenfold, compared with a conventional geostationary satellite orbit system. 11 refs.

**092872 SPECULATIONS ON FUTURE OPPORTUNITIES TO EVOLVE BRAYTON POWERPLANTS ABOARD THE SPACE STATION.** Although both Rankine and Brayton cycles, two concepts for solar-dynamic power generation, now compete to power the Space Station, this paper confines its attention to the Brayton cycle using a mixture of He and Xe as its working fluid. Such a Brayton powerplant to supply the Station's increasing demands for both electric power and heat has the potential to gradually evolve higher and higher performance by exploiting already-evolved materials (ASTAR-81C and molten-Li heat storage), its peak cycle temperature rising ultimately to 1500 K. Adapting the Station to exploit long tethers (200 to 300 km long) could yield large increases in payloads to LEO, to GEO, and to distant destinations in the solar system. (Edited author abstract) 27 refs.

**092873 SOLAR DYNAMIC POWER SUPPLY FOR ORBITING SYSTEMS WITH FREE-PISTON STIRLING ENGINE.** The Stirling cycle has been extensively developed and tested for various terrestrial applications. It is therefore believed that a free piston Stirling engine with integrated linear alternator will have sufficient potential for space power applications. A solar dynamic power system for approx. 1 kW<sub>e</sub> has been proposed for the

second German Spacelab Mission (D2) in 1990 and is further being considered as candidate for similar flight opportunities. This might be the very first in-orbit operation of a free piston Stirling engine. The actual power system configuration and operating characteristics will mainly be determined by the particular mission constraints. This paper is focussed on the concept of the proposed flight-demonstration-experiment and related areas of technological concern. General issues like overall efficiency, pointing accuracy, erosion/degradation, maintenance, replaceability, etc., are addressed as well. (Edited author abstract)

Kuczera, H. (MBB/ERNO, Ottobrunn, West Ger). *Space Technol (Oxford)* v 7 n 4 1987 p 345-350.

**092874 ADVANCED POWER SUPPLY AND DISTRIBUTION SYSTEMS FOR COLUMBUS.** The paper describes power supply and distribution systems to be used on unmanned/man-tended Columbus elements, capable of supplying 10 kW to 30 kW to a variety of users in low earth orbits (LEOs). For the definition of the Electrical Power System (EPS) challenging requirements as the provision of high power levels under hard LEO conditions, maintainability, commonality etc. are to be taken into account. These requirements are to be seen in conjunction with the Columbus IOC (initial operational capability) scenario stipulating that EPS hardware shall be used on the Polar Platform, the Pressurized Module attached to the U.S. Space Station and the Man-Tended Free Flier. According to the availability of the European technologies, the baseline in the power generation area is a photovoltaic system which provides three regulated main buses (150 V d.c.) to the users. In order to maintain power supply during eclipse phases, nickel hydrogen batteries will be used for energy storage purposes with nickel cadmium as back-up solution. (Edited author abstract) 2 refs.

**092875 PHOTOVOLTAIC POWER MODULES FOR NASA'S MANNED SPACE STATION.** Two similar space power systems able to survive the low-earth orbit environment, are being considered for NASA's Manned Space Station (SS), scheduled to begin operation in the mid 1990's. The Space Station Electric Power System (EPS) is composed of Photovoltaic (PV) Power Modules, Solar Solar Dynamic (SD) Power Modules, and the Power Management and Distribution (PMAD) System. One EPS configuration will deliver 37.5 kW of PV-based, utility-grade, ac power to SS users. A second 75 kwe PV-based EPS option is also being considered for SS deployment. The two EPS options utilize common modules and differ only in the total number of PV Power Modules used. Each PV Power Module supplies 18.75 kwe of ac power and incorporates its own energy storage and thermal control. The focus of this paper is on the general requirements and the current preliminary design configuration of the Space Station PV Power Modules. (Edited author abstract) 9 refs.

**092877 THICK DIELECTRIC CHARGING ON HIGH-ALTITUDE SPACECRAFT.** Thick dielectric charging, in which energetic electrons embed within bulk dielectrics, building up to potentials in excess of the breakdown potential of the dielectric, is shown to be a causative factor in anomalous operation of high-altitude satellites. A table of maximum expected electron fluxes in various altitude orbits is presented. Consideration of these maximum fluxes and the fact that the energy associated with a bulk dielectric breakdown is small demonstrate that bulk charging can be eliminated as a spacecraft problem through minimal shielding (400 mg/cm<sup>2</sup>) of all cables and circuit boards otherwise exposed to the environment, and through desensitizing digital logic inputs which are serviced by cables. (Author abstract) 25 refs.

**092878 ELECTRON BEAM EXPERIMENTS AT HIGH ALTITUDES.** Experiments with the electron gun on the SCATHA satellite produced evidence of beam-plasma interactions, and heating of the low-energy electrons around the satellite. These experiments were conducted near geosynchronous orbit, in the dusk bulge, and plasma sheet, with one short operation in the lobe regions, providing a range of ambient plasma densities. Data from electrostatic analyzers and the dc electric field experiment show that the satellite charged to near the beam energy in sunlight, at sufficiently high beam currents. The electrostatic analyzers showed distribution functions which had peaks or plateaus at energies greater than the satellite potential. These measurements indicate heating of the ambient plasma, at several Debye lengths from the satellite (several tens of meters), with the heated plasma then accelerated into the satellite. It is likely that at times the 'ambient' cold plasma is in fact the photoelectron sheath generated by the satellite. (Edited author abstract) 16 refs.

**092879 EVIDENCE FOR DIFFERENTIAL CHARGING ON METEOSAT-2.** Operational problems with Meteosat-1 led to a collaborative effort to furnish subsequent spacecraft with simple charging monitors and to study the geosynchronous environment in an attempt to better understand the charging process. The electron spectrometer on Meteosat-2 has yielded a continuous data set since 1982 which has clarified the role of plasmasheet electrons in the detailed current balance which controls spacecraft potentials. Continual observation of eclipse and partial shadowing features has illuminated the dominant role of photoelectrons and demonstrated that a safe clamping of differential voltages can be attained. An electron albedo index has been developed as an aid to assessing spacecraft liability to charging. The majority of anomalies experienced by Meteosat-2 are not directly caused by charging. **092880 AUTOMATIC CHARGE CONTROL SYS-**

**TEM FOR GEOSYNCHRONOUS SATELLITES.** An autonomous system to detect both absolute and differential spacecraft charging aboard high-altitude satellites, and to reduce those potentials before hazardous arcing levels are reached, is now being developed. The system will utilize a xenon-based plasma source that can be ignited without any warm-up, and that will produce a plasma capable of furnishing a neutralizing ion current greater than 1 mA. The spacecraft charging level will be detected by sensors similar to those that operated aboard SCATHA. Satellite frame potential (relative to the ambient space plasma) will be determined by an electrostatic analyzer. The flight system will be completed by mid-1988, and could be flight-tested at geosynchronous orbit in the 1989-1992 time period. (Edited author abstract) 8 refs.

**Radiation Protection**

**092881 RADIATION PROBLEMS IN MANNED SPACEFLIGHT WITH A VIEW TOWARDS THE SPACE STATION.** With the advent of a permanently manned Space Station, the longstanding problems of radiation protection in manned spaceflight have acquired an immediacy. This paper endeavors to emphasize the gaps of our knowledge which must be closed for effective radiation protection. The information that is required includes the accurate determination of the exposure inside the space station to the various components of the ionizing radiation, the evaluation of the biological importance of the different radiation qualities and the depth-dose distribution of the less penetrating component. There is also the possibility of an interaction with weightlessness. (Edited author abstract) 28 refs.

**Radiation Shielding**

**092882 RADIATION DOSE AND SHIELDING FOR THE SPACE STATION.** Significant differences in dose prediction for Space Station arise depending on whether or not the magnetic field model is extrapolated into the future. The basis for these calculations is examined in detail, and the importance of the residual atmospheric layer at altitudes below 1000 km with respect to radiation attenuation is emphasized. Dosimetry results from Shuttle flights are presented and compared with the computed results. It is recommended that, at this stage, no extrapolation of the magnetic field into the future be included in the calculations. A model adjustment, to replace this arbitrary procedure, is presented. Dose predictions indicate that, at altitudes below 500 km and at low inclination, and with nominal module wall thickness (0.125 in. aluminum), orbit stay times of 90 days in Space Station would result in quarterly radiation doses to the crew. (Edited author abstract) 12 refs.

**092886 REFLEXIONS SUR L'UTILISATION A DES FINS THEMATIQUES DE L'IMAGERIE SATELLITAIRE.** [Considerations on the Use of Satellite Imagery for Thematic Purposes]. This study is concerned with a general model of satellite data interpretation. For this interpretation, the user has to abstract a particular dimension from the landscape considered as a system. The review of some applications in remote sensing has revealed that all the algorithms used in image processing for land surveys consist of operations on three kinds of information extracted from satellite data. In cartographic applications and in land use inventories, the emphasis is laid on the spectral information. When the aim of the study is to model the geographical properties of the landscape, the analysis of spectral information is combined with analysis of the spatial information. Finally, when evolutionary studies are conducted, the temporal information is introduced. (Author abstract) In French. 57 refs.

**092887 VARIABILITY OF LANDSAT MSS SPECTRAL RESPONSES OF FORESTS IN RELATION**

**TO STAND AND SITE CHARACTERISTICS.** The use of field measures of slope angle, slope aspect, cover type, crown size and crown density is evaluated in appraising the variability of Landsat Multispectral Scanner (MSS) spectral responses for 182 sample sites within Crater Lake National Park, Oregon. Multiple linear regression models indicate that 73, 72, 71 and 57 percent of the variation in the mean response of MSS bands 4, 5, 6 and 7, respectively, was explained by the environmental variables entered into the models. In general, crown size and crown density are less important in altering spectral response than terrain orientation. (Edited author abstract) 15 refs.

Walsh, Stephen J. (Univ of North Carolina, Chapel Hill, NC, USA). *Int J Remote Sens* v 8 n 9 Sep 1987 p 1289-1299.

**092888 VEGETATION SPATIAL VARIABILITY AND ITS EFFECTS ON VEGETATION INDICES.** Landsat MSS data were used to simulate low resolution satellite data, such as NOAA AVHRR, to quantify the fractional vegetation cover within a pixel and relate the fractional cover to the normalized difference vegetation index (NDVI) and the simple ratio (SR). The MSS data were converted to radiances from which the NDVI and SR values for the simulated pixels were determined. Each simulated pixel was divided into clusters using an unsupervised classification programme. Spatial and spectral analysis provided a means of combining clusters representing similar surface characteristics into vegetated and non-vegetated areas. (Edited author abstract) 23 refs.

**092889 SOIL AND SUN ANGLE INTERACTIONS ON PARTIAL CANOPY SPECTRA.** The spectral behavior of an incomplete cotton canopy was analyzed in relation to solar zenith angle and soil background variations. Soil and vegetation spectral contributions towards canopy response were separated using a first-order interactive model and consequently used to compare the relative sensitivity of canopy spectra to soil background and solar angle differences. Canopy reflectance behavior with solar angle increased, decreased or remained invariant depending on the reflectance properties of the underlying soil. Sunlit and shaded soil contributions were found to alter vegetation index behavior significantly over different Sun angles. (Author abstract) 18 refs.

**092890 CARACTERISATION DE FORMATIONS VEGETALES MEDITERRANEEENNES A PARTIR DE DONNEES 'THEMATIC MAPPER'. UNE ETUDE DE CAS EN ANDALOUSIE (ESPAGNE).** [Characteristics of Mediterranean Vegetation Formations on the Basis of the Thematic Mapper Data. A Case Study in Andalusia (Spain)]. The study is focused on the characterization of vegetation formations in a Mediterranean area (943 km<sup>2</sup>) located in southern Spain: herbaceous canopies (rangelands), shrubby vegetation and complex woody/herbaceous formations. Vegetation formations (physiognomical units) have been characterized by their spectral responses in the six reflective TM channels and by vegetation indices. From the ratio index TM4/TM3 there has been derived a map displaying seven classes (water, bare soil and five biomass levels reflecting the hierarchy of vegetation formations). Channels TM3, TM4 and TM5 have been considered for a supervised classification into nine land-cover categories (seven vegetation formations, bare soil and water). The proportion of correct classification of vegetation formations is about 78 percent when considering test areas. In French. 20 refs.

**092893 DISCRIMINATION PROBLEMS FOR SATELLITE IMAGES.** This paper discusses the pitfalls of classifying satellite images using automatic classifiers. The discussion is illustrated by application of quadratic and linear discrimination to high resolution data produced for the National Remote Sensing Centre campaign. Within the training set there is good discrimination between most land uses, but the lack of agreement between overall results of discrimination for the two discriminators shows that measures of accuracy based on accuracy within the training set can be misleading. Cross-validation of the quadratic discriminator and calculation of between and within site measures of spectral variability also illustrate how the usual calculations may give over-optimistic measures of discrimination accuracy and spectral variability. (Author abstract) 3 refs.

**092894 LANDSAT SENSORS; EOSAT'S PLANS FOR LANDSATS 6 AND 7.** This paper describes the design configuration of the Enhanced Thematic Mapper (ETM) sensors that are presently under construction for Landsats 6 and 7. It presents an overview description of the Thematic Mappers that are currently flying on Landsats 4 and 5. The enhancements to the Landsats 6 and 7 Thematic Mappers are then described in some detail, including the implementation of a panchromatic band of detectors providing 15 m spatial resolution for both ETM sensors. The Landsat-7 ETM may include as many as five bands of thermal detectors with 120/60 m spatial resolution; the implementation and performance of this option will be discussed. The paper also provides a brief description of two new sensors that are being considered for Landsats 6 and/or 7: a low-resolution (500 m), wide-field sensor (a regional Mapper) with the Thematic Mapper's spectral-coverage, and a high-resolu-

tion (10/20 m), narrow-field, pointable Advanced Landsat Sensor (ALS) utilizing multispectral linear array technology. (Edited author abstract)

**092895 SATELLITE REMOTE SENSING IMAGERY IN PUBLIC HEALTH.** The purpose of this paper is to give a brief overview of the existing fields of the application of satellite imagery and to draw the attention of the scientific community to a new outlook for the future of public health. This outlook is based on new capacities of the space remote sensing technology, which allows us to focus its application on a new field. Further, this paper discusses the methodology for the operational application and specifies public health activities which can use this methodology. Necessary actions for establishing present capacities and limitations as a formulation of the development of new techniques are proposed. (Edited author abstract) 23 refs.

**092896 EARTH OBSERVING SYSTEM: CONCEPTS AND IMPLEMENTATION STRATEGY.** Concepts have been developed for an Earth Observing System (Eos), a fifteen year mission planned to begin in the 1990s. Diverging from previous practices, Eos is conceived as an Earth science information system where orbiting remote sensing instruments, in situ measurement devices and a data and information system are to be fused into a highly capable research tool. The Eos data and information system will have distributed elements, providing the users with remote electronic access to data services without constraining the location of the elements of the system. The implementation strategy assumes that Eos instruments are to fly on polar platforms developed as part of the Space Station complex. The global nature of Earth system science naturally implies the need for international involvement. Three Eos platforms are planned to be launched into low, polar, sun-synchronous orbits during the Space Station's Initial Operating Configuration, one to be provided by the European Space Agency and two by the United States. (Edited author abstract) 6 refs.

**092897 ERFASSUNG DER LANDNUTZUNGS-STRUKTUREN NORDWESTLICH WUERZBURG ANHAND DIGITALER, MULTISPEKTRALER LANDSAT-5-THEMATIC-MAPPER-DATEN.** [Land-Use Classification in a Region North-West of Wuerzburg Using Digital, Multispectral LANDSAT 5 Thematic Mapper Data]. Using a Landsat TM scene of July 7, 1984 the land-use of a predominantly rural area is recorded by means of digital image processing techniques. In order to distinguish a maximum of land cover types, possibilities of interactive separation of different classes, with almost similar spectral reflection, are shown. The results of the supervised Maximum-Likelihood classification as well as a color composite are superimposed with selected topographical information. Furthermore, methods of visual interpretation are presented. (Author abstract) In German. 84 refs.

**092898 INFLUENCE OF TOPOGRAPHY ON FOREST REFLECTANCE USING LANDSAT THEMATIC MAPPER AND DIGITAL TERRAIN DATA.** The relationship between forestry variables and the response of Thematic Mapper bands is analyzed over selected mountainous forest sites with a view to improving current models. Forestry stand species and age information was collected for 250 sites in a region with slopes up to 35 degrees and a variety of aspects. Spring and summer

Thematic Mapper imagery over the area were used; these data contain a wealth of information related to species and age, and topography. A digital elevation model was compiled with a resolution of 30 metres in order to study the relationship between reflectance, the variable of interest, and the local sun/surface/sensor geometry. The influence of the age on the apparent reflectance distribution is analyzed: reflectance globally decreases with stand age, especially for TM4, TM5, and TM7. (Edited author abstract) 12 refs.

**092900 FUTURE ROLE OF SATELLITES.** Remote sensing of the sea surface, and hence oil slicks, can be carried out from any height: ground level (either on shore or from a ship), from an aircraft or from space. Each of these options possesses distinct advantages and disadvantages and any comprehensive monitoring system will in all probability involve elements of all three. This paper is concerned with the role of remote sensing satellites in any such system. It has been shown that polar orbiting spacecraft do not have a role in response to an oil spill but that they do have a possible use in routine monitoring. A system of two satellites (similar to the proposed polar platform) has been proposed which would enable such monitoring to be done in UK waters. The instrument needed would be similar to the SAR-C proposed for the ESA polar platform, for which both resolution/swath and incidence angle can be varied. 5 refs.

## Robot Applications

**092901 CONTINUOUS PATH CONTROL OF SPACE MANIPULATORS MOUNTED ON OMV.** Theoretical analysis of the formulation of kinematics for a manipulator mounted on a satellite is presented. To solve the inverse kinematics, the authors define a new generalized Jacobian matrix, and utilizing this generalized matrix, the problem can be treated analytically. The authors then verify the method proposed here in the simulation study. Finally, they also discuss the several points which are indispensable for further investigations. (Edited author abstract) 3 refs.

## Scheduling

**092902 SCHEDULING EXPERIMENTS ON THE SPACE STATION.** The objective of this research is to schedule laboratory experiments on the space station in a power starved environment. Experiments on the space station will compete for electric power and other scarce resources. A principal investigator for an experiment may submit numerical preferences for different periods in which his/her experiment can be started. Weighted preferences are computed by multiplying these preferences by a numerical priority assigned to the experiment by a space station management committee. The scheduling problem is formulated as an integer programming problem with 0/1 variables. (Edited author abstract) 10 refs.

## Simulators

**092903 GOULD ES1000 RECORDER IS OUT OF THIS WORLD.** A Gould ES1000 recorder is playing a vital role in reproducing the dynamic parameters generated by a satellite simulator belonging to the MATRA ESPACE Data Processing and Ground Division in Toulouse, France. The Gould ES1000 was the perfect choice, not only because it could easily fulfill the basic requirements but also because it offered additional ones as well: it executes multi-channel recording in analog format; its digital inputs permit full control by a computer via a standard IEEE 488 bus; and it has an IT164 four-channel digital input, IT488 remote control and M200 alphanumeric printing.

## Stability

**092904 STABILITY OF A SATELLITE WITH AN AEROGYROSCOPIC ORIENTATION SYSTEM IN A CIRCULAR ORBIT.** We consider the problem of uniqueness of stable equilibrium orientation of a satellite moving in a circular orbit, that is equipped with an areostabilizer and two single-degree-of-freedom gyroscopes, mounted in a certain fashion and attached to the housing of the satellite by an elastic coupling. We obtain sufficient conditions imposed on the system parameters, such that only the so-called zero position of the satellite is stable, while other positions are either impossible or unstable. (Author abstract) 2 refs.

Biryukova, M.P. *Mech Solids* v 22 n 2 1987 p 9-16.

**092905 STABILITY OF STATIONARY MOTIONS OF AN ELASTIC RING IN THE PLANE OF A CIRCULAR ORBIT.** The stability of the stationary motions of a satellite in the form of an elastic rod bent into a ring is studied in the linear approximation taking into account the deformability of the system. Gravitational and aerodynamic forces are taken into account. If there is no aerodynamic resistance, then from the Jacobi integral it may be concluded that the motion is stable in the sense of Lyapunov. In the general case the partial differential equations can be reduced to ordinary differential equations by Galerkin's method, after which the stability of the corresponding trivial solution can be studied in the standard manner. It turns out that the aerodynamic forces cause the stationary motion to be unstable, and this instability cannot, for all practical purposes, be eliminated by damping owing to dissipation of energy in the rod material. **092906 EXAMINATION OF POSSIBLE SOLAR WIND SOURCES FOR A SUDDEN BRIGHTENING OF COMET IRAS-ARAKI-ALCOCK.** Possible solar wind sources for a sudden global brightening of Comet IRAS-Araki-Alcock are examined. No increases in solar wind momentum flux, solar energetic particles or solar activity occurred coincident with these brightenings. The only change in the solar wind coincident with the brightenings was a rotation of the interplanetary magnetic field to a more flow-aligned state. If this rotation did not lead to the cometary brightening, the brightening must have been intrinsic to the comet. (Author abstract) 11 refs.

**092907 ATMOSPHERIC EFFECTS ON LANDSAT TM THERMAL IR DATA.** The components of atmospherically attenuated target radiance and the path radiance emitted by the atmosphere are calculated to explain the fact that for certain meteorological conditions, properly calibrated thermal IR (infrared) data gathered from aircraft and spacecraft altitudes provide accurate temperature measurements of surface water bodies even when atmospheric corrections are not applied. Results show that although the 8-14- $\mu$ m atmospheric window is far from being transparent (< 50% transmission), the amount of atmospheric path radiance may be equal to the amount of attenuated target radiance. Errors in remotely sensed temperatures introduced by atmospheric effects are shown to be smaller than or of the same order of magnitude as those errors caused by sensor noise and the effects of applying a cubic convolution during the process of converting the TM (Thematic Mapper) data from A-type to geometrically corrected P-type data format. 28 refs.

**092908 NOISE-RESISTANT UNIT AUTOMATICALLY TRACKS GEOSYNCH SATELLITES.** Earth stations used for tracking geosynchronous satellites must be highly accurate, noise-resistant, and reliable, yet still be cost-effective. Conventional stations, using step-track algorithms, have limited accuracy because of demands for low-cost, simplified hardware. Monopulse systems, although more accurate, are more costly. However, a new tracking algorithm not only improves the accuracy, but also saves money by using similar cost-effective, step-track hardware. 3 refs.

**092911 IMPROVED METHOD FOR DETECTING CLEAR SKY AND CLOUDY RADIANCES FROM AVHRR DATA.** To obtain accurate estimates of surface and cloud parameters from satellite radiance data a scheme has to be devised which identifies cloud-free and cloud-filled pixels (i.e. fields of view). Such a scheme has been developed for application on high resolution (1.1 km pixel) images recorded over Western Europe and the North Atlantic by the AVHRR on the TIROS-N/NOAA polar orbiters. The scheme consists of five daytime or five night-time tests applied to each individual pixel to determine whether that pixel is cloud-free, partly cloudy or cloud-filled. The scheme has been successfully applied to data for all seasons, including images with unusually cold or warm surface temperatures. To assess the method both daytime and night-time NOAA-9 passes over the U.K. were obtained for a week in April 1985 and some

results from this data set are presented here. (Edited author abstract) 46 refs.

**092914 LOW COST CAPTURE OF DATA FROM METEOSAT.** The Meteosat satellite is parked in a geostationary position over the equator at zero meridian and views a world disc comprising, mainly, Africa and Europe. The author describes a reliable capture of data from satellites using inexpensive hardware and its distribution around a laboratory of independently operating data collection/image processing workstations. In this article discussion is limited to data capture from Meteosat although we are also involved in collecting data from the NOAA series of orbiting satellites.

Stephenson, John (Univ of Bradford, Engl). *Comput Bull (London 1986)* v 4 pt 2 Jun 1988 p 22-23.

**092915 USE OF SATELLITE AND RADAR IMAGES IN OPERATIONAL PRECIPITATION NOWCASTING.** Remote sensing provides spatial and temporal resolution data. Within meteorology, these two qualities have simulated the development of a new approach to short range forecasting termed 'nowcasting' FRONTIERS is one example of a real time precipitation nowcasting system, based on METEOSAT and ground based weather radar imagery. (Edited author abstract). 7 Refs.

Howes, S. (Logica Space & Defence Systems Ltd, London, Engl). *J Br Interplanet Soc* v 41 n 10 Oct 1988 p 455-460.

**092916 APT ON THE POLAR ORBITING WEATHER SATELLITES.** The author recounts the historical development of meteorological satellites to describe the need for automatic picture transmission (APT). The idea for weather observations from a satellite originated with a small group of meteorologists of the U.S. Army Signal Corps Research and Development Lab. at Ft. Monmouth, N.J., and resulted in the design of Vanguard II. The Tiros and TOS series of satellites, and the design of Nimbus, are briefly reviewed. A faster picture dissemination than was available at that time was needed, sparking the development of APT. All three systems, existing polar orbiting weather satellites, APT, and geosynchronous weather satellites, are discussed. It is noted that while the idea of APT and the polar orbiters was stimulated by the need for immediate data access, a companion goal was to produce a ground station at the lowest possible cost. Descriptions are given of the APT

system, its evolution, and the subsequent benefits desired.

**092917 G-300, THE FIRST FRENCH GETAWAY SPECIAL MICROGRAVITY MEASUREMENTS OF FLUID THERMAL CONDUCTIVITY.** On Earth thermal conductivity measurements on liquids are difficult to perform because of thermal motions due to convection. In microgravity the convection due to buoyancy is evanescent and we expect a strong lowering of Rayleigh and Nusselt numbers. Three low viscosity liquids were selected to carry out the measurements: distilled water (standard), and two silicone oils. We use a modified 'hot plate' method with a simplified guard ring. Comparisons between Earth and orbit results may help to understand the convection occurrence in our cells. G-300 payload is cantilevered from the experiment mounting plate (EMP) and it includes: four struts, an intermediate plate, a bottom plate with four bumpers, a battery box, an electronic rack and six experimental cells assembled in twin-packs thermally coupled with the EMP. (Edited author abstract) 5 refs.

**092919 MARANGONI INSTABILITY WITH NON-UNIFORM VOLUMETRIC ENERGY SOURCES DUE TO INCIDENT RADIATION.** The effects of non-uniform volumetric energy sources, temperature-dependent viscosity and surface-tension on Marangoni convection in an incompressible fluid layer are studied. The nonlinear temperature profile arises from external incident radiation. The critical conditions for the onset of Marangoni instability in a microgravity environment ( $10^{-6}$ - $10^{-3}$  g) are determined numerically after a normal mode-type linear stability analysis. The perturbation equations are solved as an optimal control problem in the calculus of variations using Miele's sequential gradient-restoration algorithm (SGRA). The results indicate that viscosity plays a significant role in Marangoni convection relative to surface-tension. (Edited author abstract) 23 refs.

**092920 MASS TRANSPORT PHENOMENA BETWEEN BUBBLES AND DISSOLVED GASES IN LIQUIDS UNDER REDUCED GRAVITY CONDITIONS.** This paper describes the experimental and analytical work that has been done to establish justification and feasibility for a shuttle mid-deck experiment involving mass transfer between a gas bubble and a liquid. The experiment involves the observation and measurement of the dissolution of an isolated, immobile gas bubble of specified size and composition in a thermostated solvent liquid of known concentration in the reduced gravity environment of earth orbit. The primary objective

of the experiment is the elimination of convective effects that occur in normal gravity. The results will yield information on transport under conditions of pure diffusion. (Edited author abstract) 36 refs.

## SAWMILLS

### Design

**092922 TESTING DESIM FOR DESIGNING AND SIMULATING THE OPERATION OF HARDWOOD SAWMILLS.** The DESIM system was tested to determine how realistically it could simulate the operation of a hardwood sawmill. We compared the individual values for a number of test variables from one 10-hour operating shift with the corresponding frequency distributions for 100 simulated 10-hour shifts. The actual values for all of the test variables fell within two standard deviations of the mean simulated values. Since the actual values and the mean simulated values are reasonably close, the DESIM system did realistically simulate the operation of the test mill. (Author abstract). 8 Refs.

Adams, Edward L. (USDA, Princeton, WV, USA). *For Prod J* v 38 n 7 pt 8 Jul 8 1988 p 41-45.

### Economics

**092923 CAPITAL BUDGETING PRACTICES OF SMALL- TO MEDIUM-SIZED SAWMILLS AND PALLET MILLS.** Sawmills and pallet mills in the eastern and southeastern United States were surveyed to determine their capital budgeting practices. It was found that discounted cash flow techniques have not been extensively adopted as primary methods of investment analysis. Nondiscounted payback period was the most extensively used quantitative method of analysis. For investments requiring less than \$50,000, 47.5 percent of the firms used no quantitative method. The majority of firms compared the expected return on an investment to a minimum rate of return, but this minimum was often determined nonquantitatively. Firms most often account for the risk of an investment by subjective means. Firms with less than \$50 million in annual sales were tested for a relationship between investment decisionmaking or risk accounting technique and firm size, location, and type. No statistically significant relationships were found. (Author abstract) 26 refs.

Bush, Robert J. (Southern Illinois Univ, Carbondale, IL, USA); Sinclair, Steven A. *For Prod J* v 37 n 10 Oct 1987 p 68-71.

**092924 MODELING SAWMILL PRODUCTION, COSTS, AND PROFITABILITY AS A GUIDE TO PREPARING BIDS FOR TIMBER.** An empirically based sawmill simulation model was developed to assist buyers in determining bids for specific tracts of timber. The model is deterministic and incorporates physical production functions and cost and product price data important

in sawmill operations. The model was used in a study of competitive bidding for a sample of timber sales and sawmills in southern New England. Results show that log size has an important effect on sawing production and costs. Competition for high quality timber was keen and profit margins estimated for individual mills were considered acceptable to both buyer and seller, and were closely grouped. (Edited author abstract) 12 refs.

Howard, Andrew F. (Univ of British Columbia, Vancouver, BC, Can). *For Prod J* v 38 n 3 Mar 1988 p 29-34.

### Efficiency

**092925 COMPARISON OF SAWING VARIABLES BY REGION OF THE UNITED STATES.** Sawing variables obtained from 650 studies of softwood sawmills were compared by region of the United States. The term sawing variable is used here to describe certain factors of the sawmilling process that determine the efficiency with which wood fiber is converted to lumber. Variables were headrig kerf, resaw kerf, total sawing variation, oversizing/undersizing, fixed-head planer allowance, and rough green size. Comparison-of-means tests were used to compare regional values of these sawing variables. Significant differences among regions were found for all sawing variables. It was also found that total sawing variation for 8/4 lumber was significantly lower than for 4/4 lumber at the same study sawmills. 13 refs.

### United States

**092926 RELATIVE SOFTWOOD SAWMILL CONVERSION EFFICIENCY BY REGION OF THE UNITED STATES.** Accurate assessment of future trends in the supply of forest products depends, in part, on knowledge of regional softwood sawmill conversion efficiency. Data from 650 sawmill studies carried out in the years 1973 through 1983 were analyzed to obtain estimates of regional conversion efficiency. Statistical tests, both adjusted and unadjusted for log size, showed that significant regional differences existed. The fact that conversion efficiency adjusted for log size differed among regions indicates that processing technologies, in the form of improved processing methods, fibersaving machinery, and/or improved quality control programs, also differed among some regions. (Author abstract) 21 refs.

**SAWS** See Also METAL CUTTING.

**092927 STUDY ON THE HEAT TREATMENT OF HAND-SAW BLADES MADE OF DUAL-METALS.** On the basis of the CCT-diagrams of W6Mo5Cr4V2 and 50CrNiMoVA steels, by adopting different heat treating processes, comparative tests on hardness, microstructure and machinability were carried out. It is found feasible to employ through heating for the saw blades in the salt bath, but if the hardness of the teeth is higher than HRC 67, they easily break, and if it is lower than HRC 62, their wear resistance is poor. When hardened saw blades are tempered or nitrocarburized, the procedure is beneficial for increasing mechanical property and cutting life. (Edited author abstract) In Chinese. 5 refs.

Yang, Ke-fu; Qin, Heng-wu. *Jinshu Rechuli* n 6 Jun 1987 p 29-32.

**092928 MULTIWIRE SAW FOR THE PRODUCTION OF ULTRASOUND TRANSDUCERS.** Ultrasound echography is now an important tool in medical diagnostics, e.g. in cardiology, gynaecology and radiology. In this paper a multiwire saw is described which is

capable of separating up to 600 acoustic elements over a 120 mm range. The saw itself automatically controls all kinds of sawing parameters such as wire tension, wire speed, etc. in order to minimise wire breakage and to optimise sawing results. With this saw the production costs are low, small forces are exercised on the product, hardly any heat is produced, the sawing groove is very smooth and no limitation exists as to the sawing depth. (Edited author abstract) 2 refs.

den Ouden, A. (Erasmus Univ, Rotterdam, Neth); Brinkman, J.F.; Niesing, R.; Lancee, C.T.; Bom, N. *J Phys E* v 20 n 12 Dec 1987 p 1457-1461.

**092929 DIE CHANCE DES KREISSAEGENS: TRENNEN UND FERTIGEN.** [Chance of Circular Sawing: Severing and Manufacturing]. Based on a statement an expert in severing techniques made 10 years ago, it is intended to investigate here the development of severing techniques since then. In the midst of a substantial change that forced the circulatory severing techniques into the background by preferring translatory techniques, it is highly justified to raise the question for a new position of circular sawing within the severing technologies in general. The statement was: 'Sawing is in most cases a preparatory operation and in rare cases only a finishing operation. Sawing errors can be corrected during subsequent operations. The objective in preparatory machining by sawing is to prevent the subsequent operations of turning or milling to become more costly due to sawing ...'. Consequent application of circular sawing can now minimize or even eliminate subsequent machining needs. One of the chances involved with circular sawing appears to be that it can combine severing and manufacturing in the cut-off process. If appropriately conceived, this cut-off process can thus also perform a machining operation which would have to be made subsequently by means of another machining method if a different severing technique was used. (Edited author abstract) 18 refs. In German.

**Applications** See INTEGRATED CIRCUIT MANUFACTURE—Equipment.

### Design

**092930 GUIDED SAW HUNTING.** A new design factor affecting the accuracy of lateral positioning of a guided circular saw is identified. Conventional guide configurations lead to a 'hunting' behavior, where the sawblade does not remain perpendicular to the drive shaft, but always drifts to one side or the other. This behavior is explained using a simple geometrical model, and methods of preventing or minimizing the effect are described. (Author abstract)

**092931 BUILDING OWNER SAVES MONEY.** Diamond wire was first used in the quarry and for block squaring on soft rock types, mainly marbles, travertine and the like. With further advances it proved possible to perfect the technique to the point where it can now be economically applied to hard rock. Potential applications for the diamond wire saw are also to be found in the construction industry, especially where reinforced concrete walls over 500 mm thick have to be removed - an operation which previously required diamond stitch drilling or wall sawing with the blade penetrating from both sides. Diamond wire sawing can offer significant advantages over stitch drilling and conventional wall sawing for

reinforced concrete over 500 mm thick. The owner of a building in Lucerne, Switzerland, opted for the new technique to cut an opening of  $7.02 \times 4.45$  m.

Schaffner, J.; Blaser, E. *Ind Diamond Rev* v 47 n 521 1987 p 163-164.

**092932 CHAIN SAWING FOR HOUSES.** Mining below ground can affect dwellings on the surface. A new sawing method for creating expansion and contraction joints in the walls of terraced houses, to reduce the effects of soil movement, has been tried in Germany. People who live in mining areas generally appreciate the risks, but in view of the high costs and general inconvenience, often for a lengthy period, new techniques are constantly sought to enable the tensions to be released in house structures in a way which is both simpler and causes minimum inconvenience. The use of diamond sawing techniques to make a parting line has been discussed for a long time now in Germany, but so far practical tests have not produced satisfactory results.

Weber, U. (Ruhrkohle AG); Zilm, F. *Ind Diamond Rev* v 47 n 522 1987 p 214-215.

**092933 CENTRALIZATION AT BURLINGTON.** Prior to 1984, Burlington Slate operated separate processing facilities at each of its seven quarries, spread over an eighteen mile radius. The company then invested in a £1 million scheme to centralize all slate processing at its headquarters at Kirkby-in-Furness, the first phase of which was reported in IDR in 1985. The move by Burlington to centralized processing appears to be paying dividends. Turnover for 1986 was over \$5 million, an increase on the \$4.2 million the previous year. Over 60% of production is exported and it is interesting to note that in most years, the turnover figure is boosted by a single major project such as the \$2.2 million Heinz Centre. The facilities at Kirkby are now more than capable of maintaining the present production figures. Architectural products account for around 70% of turnover and as long as the demand for slate continues, Burlington is confident it can continue to meet that demand. 3 refs.

Jennings, Martin. *Ind Diamond Rev* v 47 n 522 1987 p 216-218.

**092934 BACK TO THE STONE AGE.** Almost a hundred years ago, the founder of the Halifax, UK company Marshalls Mono Ltd started production of natural York stone paving from a local quarry. This set in motion a process which eventually led to the establishment of one of Britain's largest suppliers of precast concrete paving, a material which became so popular that it led to the shutdown of natural stone quarrying ten years ago. Recent changes in market trends, however, prompted a rethink. The author reports on how the discovery of extra reserves of stone, coupled with advantages brought about by diamond sawing, have led to Marshalls Mono getting back into the natural stone business. (Author abstract) 2 refs.

Jennings, Martin. *Ind Diamond Rev* v 47 n 522 1987 p 221-222.

**092935 STUDY ON MACHINING CHARACTERISTICS OF DIAMOND ABRASIVE WIRE.** The basic characteristics of diamond abrasive wire in the case of constant pressure plane cutting-off operation with a reciprocation type wire saw are experimentally studied. The cutting-off tests for some selected workmaterials are carried with and without coolant at various wire-speeds, wire-tensions and normal forces. The abrasive wire of 200µm in nominal diameter which has one layer of copper bonded diamond grains around high-strength steel core of 3.1 GPa is used for the experiments. Major experimental results are as follows, (1) The ratio of tangential force to normal force is decided by material of workpiece and wear of abrasive wire, while it slightly depends upon wire running speed, wire tension and normal force. (2) The area cut off by same wire-running-length is proportional to normal force. (3) Machining without coolant shows much lower cutting ability than that with coolant. (Edited author abstract) In Japanese. 8 refs.

## Foundations

**092938 AUFSCHUETTKISSENGRUENDUNG VON SAELEGATTERFUNDAMENTEN.** [Gang Saw Foundations on Sand Paths]. The paper discusses the problem of the discrepancy between the calculated and the measured values in the case of gang saw foundations placed on sand pads. The author points out that the universally used calculation model for block foundations under non-percussive working machines frequently requires a thorough analysis of the elastic properties of the subsoil. In such cases it is advisable to carry out on-site examinations of the subsoil. (Author abstract) In German. 6 refs.

Falkowski, Jozef (Technischen Hochschule, Koszalin, Pol). *Bautechnik* v 65 n 2 Feb 1988 p 66-68.

**092939 EINFLUSS DER TRAEGERKRAEFTE HOEHERER ORDNUNG.** [Influence of Higher-Order Inertia Forces on the Oscillation Amplitudes of Gang Saw Foundations]. The paper deals with the problem encountered when taking higher-order exciting forces into consideration in the design of foundations to be placed under gang saws and other low-speed crank-operated machines. The theoretical analysis and experimental measures indicate that it is useful to consider only first-order and second-order exciting forces. This simplifies the computation process while maintaining a level of accuracy which is sufficient for engineering practice. (Author abstract) 4 refs. In German.

## Manufacture

**092940 PLCS SPEED CHAIN SAW TESTING, INCREASE PRODUCTION EIGHTFOLD.** Stihl, Inc., a manufacturer of gasoline-operated chain saws, has changed the control of its saw testing from manual to programmable controller (PLC) based operation. As a result, they have cut 3¼ minutes from the test cycle and boosted the productivity of their in-line test standards from 15 units/hr to 120 units/hr. Quality control has also improved because test results and adjustments are now more accurate, consistent, and traceable. The 3.5 min. labor saving in testing represents about a 10% productivity gain in the overall assembly operation.

Mueller, Peter K. (Stihl Inc, Virginia Beach, VA, USA); Gosnell, Rodney. *Chilton's I&CS* v 61 n 3 Mar 1988 p 81-82.

**092941 DAS SAEGBAND: VOM WEGWERF-ARTIKEL ZUM PRAEZISIONSWERKZEUG.** [Sawband: from a Throwaway Article to a Precision Tool]. Band sawing has become a competitor for previously leading serving techniques. This would be unimaginable without the sawband as a tool. A decision change from a simple throwaway article to a precision tool has commenced here. Important expectations are held of the sawband of the future. Basic studies to date have been dealing mostly with geometry and mechanics of machine, process and tool, but the material technology of the tool usually was treated with neglect. However, it is exactly this technology that will make the development progress. (Author abstract). 13 Refs. In German.

## Thickness Measurement

**092944 ERRORS IN ESTIMATING THICKNESS PARAMETERS FOR SAW MATERIALS FROM A RESTRICTED NUMBER OF BLADE MEASUREMENTS.** This paper examines the errors for three methods of determining the thickness parameters for saw materials. These include: (1) direct parameter estimation from a restricted number N of measurements made at equally separated points along the blade (2) direct estimation from an indefinitely large number of measurements made on a restricted length L near the root or crest and (3) statistical estimation from a restricted number N of measurements made at equally separated points along the blade. 4 refs.

Kovzun, N.I. *Meas Tech* v 30 n 3 Mar 1987 p 211-214.

## Vibrations

**092945 BASIC STUDY ON VIBRATION MULTI-WIRE SAWING USING WIRE FIXED DIAMOND GRAINS.** A vibration multiwire sawing machine using wire-fixed diamond grains was developed for cutting hard and brittle materials. The underlying operational principle of the machine and some experimental results are described. 2 refs.

Ishikawa, Ken-ichi (Kanazawa Inst of Technology, Kanazawa, Jpn); Suwabe, Hitoshi. *Bull Jpn Soc Precis Eng* v 21 n 3 Sep 1987 p 214-216.

**092946 VIBRATION COMPARISON OF TWIN-CYLINDER AND SINGLE-CYLINDER CHAINSAWS.** A twin-cylinder chainsaw was evaluated to determine the vibration levels transmitted to the

operator. The saw vibration was compared with two different types of single-cylinder saws in a static bench test and in a dynamic buckling test. The tests showed a significant reduction in vibration at the handles of the twin-cylinder saw model as compared to the single-cylinder saws. (Author abstract) 8 refs.

Stokes, Bryce J. (US Forest Service, Auburn, AL, USA). *Trans ASAE* v 30 n 6 Nov-Dec 1987 p 1619-1623.

**092947 SELF-EXCITATION IN GUIDED CIRCULAR SAWS.** The paper presents the results of an experimental and analytical study into the vibrational characteristics of guided rotating saw blades that are not perfectly flat. Experimental results are presented that show the nature of the vibrations induced by the interaction between the guides and the blade. An analytical model is developed that includes the effect of the interaction between the guide and the blade, and this model may be used as a design tool in avoiding the self-excited resonances that exist in the coupled blade/guide system. (Author abstract). 8 Refs.

Lehmann, B.F. (Univ of British Columbia, Vancouver, BC, Can); Hutton, S.G. *J Vib Acoust Stress Reliab Des* v 110 n 3 Jul 1988 p 338-344.

**092948 CONTROL OF CHAIN SAW VIBRATION.** Vibration transmitted to the hands when using hand tools such as chain saws is a major health hazard in the forest industry. Several factors such as the type of chain saw, speed, and type of wood were found to be relevant in evaluating the vibration level and are included in an ISO standard. This article describes the effects of the sharpness parameters, horizontal angle, vertical angle and depth gauge, on the vibration level based on data obtained in our laboratories. (Author abstract). 10 Refs.

## Applications

**092950 TRAGGERUESTE - TECHNISCHE ANFORDERUNGEN UND MOEGLICHKEITEN.** [Supporting Scaffolds - Technical Requirements and Scope of Application]. Supporting scaffolds are to serve as temporary platforms for concrete structures while the concrete is setting. A round-up is presented on their application, the demands on functional performance and safety. Further, design concepts and their main features are dealt with. A special version, a form traveler for segmental bridge construction and its functional features are set forth. (Author abstract) In German.

Moser, Egon. *Str Tiefbau* v 41 n 7-8 Jul-Aug 1987 p 16-18, 23-24.

**Modular Construction** See CONCRETE CONSTRUCTION—Forms.

## Structural Analysis

**092951 ERGAENZENDE UNTERSUCHUNGEN ZU KUPPLUNGEN FUER GERUESTROHRE.** [Supplementary Studies of Couplers for Scaffolding Tubes].

The correlation between the tightening torque and the normal force in the screw of screw couplers is treated especially for repeated tightening. In addition, the decrease in the pretensioning force as a function of time is shown for coupler tubes made of steel and aluminum. A numerical approximation is introduced which treats the coupler as a double-shear friction connection. Regarding the torsional stiffness of right angle couplers the correlation between moment and angle is given as hysteresis loops for the range of positive and negative bending moments. In conclusion, the interaction between the different forces and the bending moment a right-angle coupler can transmit is discussed. (Edited author abstract) In German. 18 refs.

**092954 STANDARD BALANCES WITH UPPER SCALE LIMITS UP TO 10 kg.** The Czechoslovak Metrological Institute has set up a standard balance employing the substitution principle to determine the mass of the working standard and to check and certify first-class substandard weights of mass from 1 to 10 kg. The balance has upper and lower ends joined by three rods. Between the rods is a guide column for the weight displacement mechanism. The bearing plate is mounted on the upper end, on which the middle prism in the balance arm rests during the weighing. The balance employs a two-prism duralumin arm with adjustable counterweights. A major condition for obtaining high accuracy and sensitivity is correct and careful adjustment of the main units: prisms, supports, clamping bearings, mobile section of suspension, rotating table, etc. The balance has been used in the simultaneous calibration for two sets of weights of mass 1, 2, 5, and 10 kg made of nonmagnetic stainless steel. The results were processed by least squares. The standard deviation of the values calculated from the differences between the measured values and those given by the equation was  $\pm 0.15$  mg.

Spurny, R. *Meas Tech* v 29 n 2 Feb 1986 p 90-92.

**092955 MASS MEASURING ON CONVEYOR BELTS.** The article presents an overview of mass measuring on conveyor belts. It deals with the basic weighing equation and the various components of a mass-measuring system. The regulations pertaining to payment massme-

ters by the Department of Trade and Metrology are explained, and the importance of weighing accuracy is highlighted by a typical example from within Eskom. A general overview of mechanical, electro-mechanical, hybrid and nuclear massmeters is given, and the article concludes by emphasizing the importance of the correct maintenance of conveyor massmeters. (Edited author abstract) 5 refs.

Fraser, Max. *S Afr Mech Eng* v 38 n 1 Jan 1988 p 43, 45, 47-48.

**092956 HIGH ACCURACY WEIGHING AND HANDLING SYSTEM FOR BISCUIT MANUFACTURE.** The article describes a recently designed and installed automated multi-ingredient weighing and handling system, the Neu system which features high throughput with very high weighing accuracies of both solid and liquid materials. It feeds seven weighed ingredients into a new Vicars mixer, one of a series of mixing units which prepare dough for biscuit manufacture. The weighing system comprises a load cell lever assembly, fitted to the high speed mixer. The process is controlled automatically by a programmable logic controller (PLC), equipped with visual display screen. The controller supplies all operator information and monitors the total weight of ingredients in the mixer, as well as the net weight of each ingredient as it is fed into the unit.

Giles, A.C. (Neu Engineering Ltd, Woking, Engl). *Bulk Solid Handl* v 8 n 1 Feb 1988 p 61.

**092957 SAMPLING AND WEIGHING OF MINERAL CONCENTRATES.** While the variance is the most basic measure for precision, more transparent measures such as coefficients of variation, and confidence intervals and ranges, are frequently applied. Statistical tests differentiate between random variations that are intrinsic to a measurement process, and systematic errors that should be avoided if at all possible. Loss prevention and control is a logical approach to assessing the risk to lose due to systematic errors that should be eliminated, and due to random variations that can be reduced at a cost. The accuracy and precision characteristics of wet weights, moisture contents and metal grades for consignments of mineral concentrates are discussed, and their impact on the risk to lose are addressed. (Edited author abstract) 1 ref.

Merks, Jan W. (Matrix Consultants Ltd, Vancouver, BC, Can). *Bulk Solid Handl* v 8 n 2 Apr 1988 p 179-185.

**092958 ACCURACY AND TOLERANCES OF WEIGH-IN-MOTION SYSTEMS.** Tolerances for a 95 percent confidence level were derived after the system had been calibrated to yield a zero mean of differences in the weigh-in-motion wheel weight estimates and the corresponding static wheel weights. The concept of use tolerances, which allow for the probable error in both the static weight measurement and the weigh-in-motion weight estimate, is presented. Tolerances for high-speed weigh-in-motion, intermediate-speed weigh-in motion, and low-speed weigh-in-motion scales at the experimental site are tabulated. (Edited author abstract) 8 refs.

Izadmehr, Bahman (Univ of Texas at Austin, Austin, TX, USA); Lee, Clyde E. *Transp Res Rec* 1123 1987 p 127-135.

**092959 PRACTICAL UNCERTAINTY LIMITS TO THE MASS DETERMINATION OF A PISTON-GAGE WEIGHT.** The mass of a 590-g piston-gage weight was determined with a standard error of 0.057 mg (0.1 ppm). The sources of error are carefully examined. These include air-buoyancy corrections, physically adsorbed surface moisture, and air-convection within the weighing chamber. The authors conclude that significant

improvement cannot be realized with the conventional weighing techniques available to most piston-gage users. (Edited author abstract). 12 Refs.

Davis, R.S. (NBS, Gaithersburg, MD, USA); Welch, B.E. *J Res Natl Bur Stand (US)* v 93 n 4 Jul-Aug 1988 p 565-571.

**092960 DEVELOPMENT OF A 20-TON-CAPACITY LOAD-CELL-BASED WEIGHING SYSTEM FOR IAEA FIELD USE.** Based on results of an International Atomic Energy Agency (IAEA) field test of the prototype 20-ton-capacity Load-Cell-Based Weighing System (LCBWS), a modified LCBWS is being configured for routine IAEA field use in verifying the masses of 10- and 14-ton UF<sub>6</sub> cylinders. The modified system is being designed to meet IAEA objectives for accuracy and portability as well as to meet facility operating safety conditions. To best meet these design requirements, a comprehensive survey of commercially available weighing equipment was conducted. Detailed equipment specifications for 25 load cells from 15 manufacturers, for 5 digital crane scales from 3 manufacturers, and for 7 digital weight indicators from 5 manufacturers were compared. (Edited author abstract) 3 refs.

**Automation** See Also IRON ORE TREATMENT—Sintering.

**092961 DRY INGREDIENT WEIGHING.** Computerization has certainly played the single most important role in the automation of micro and minor ingredients followed closely by the advances in scale and feeder equipment design. There are numerous electronic companies presently selling dedicated industrial grade batching controllers. These controllers are multi-industry adaptable, reliable and able to provide greater control of your batching operation. Numerous variations in scale hopper design configurations can be found as well as variety of feeder designs.

Anderson, Carl E. (Agra Products Int Inc, Minneapolis, MN, USA). *Bulk Solid Handl* v 8 n 1 Feb 1988 p 60.

## Calibration

**092962 CALIBRATION AND ACCURACY TESTING OF WEIGH-IN-MOTION SYSTEMS.** Recent calibration techniques are outlined and a different approach is advocated, based on random vehicles. A statistical appraisal of the approach is discussed. A new technique is described for self-calibration of weigh-in-motion systems, based on the fact that loads on certain axles of particular truck classes show relatively little variation. The questions of weigh-in-motion accuracy appraisal and weigh-in-motion performance standards are addressed. An accuracy 'funnel' for the assessment of weigh-in-motion performance is proposed. (Edited author abstract) 9 refs.

Davies, Peter (Castle Rock Consultants, Phoenix, AZ, USA); Sommerville, Fraser. *Transp Res Rec* 1123 1987 p 122-126.

**092963 ON-SITE CALIBRATION OF WEIGH-IN-MOTION SYSTEMS.** A pronounced improvement in the accuracy with which weights were estimated by the high and intermediate systems was achieved when six loaded five-axle tractor-trailer trucks, chosen randomly from the traffic stream, were used as the basis for calibration compared with multiple runs of the same loaded two-axle, single-unit test truck. The variability in weigh-in-motion weight estimates was not affected appreciably by the type of moving-vehicle loading that was used as the basis for calibration. Static-weight loading is recommended for low speeds of weigh-in-motion calibration, and moving-vehicle loading is recommended for practicable on-site calibration of higher-speed

weigh-in-motion systems. (Edited author abstract) 5 refs.

Izadmeh, Bahman (Univ of Texas at Austin, Austin, TX, USA); Lee, Clyde E. *Transp Res Rec* 1123 1987 p 136-144.

**Computer Applications** See Also FLOW OF WATER—Nozzles; SILOS—Inventory Control.

**092964 BATCHING SYSTEM FOR GLASS/CHEMICALS.** The heart of the weighing and batching system is a Philips Microcomputer Batching Controller (MBC) which controls the weighing and batching of the raw ingredients - various cullets (scrap and bottle glass), chemicals and water - in their correct weights and proportions. Various products require various recipes, while also the recipes will change due to the quantity of the raw materials. This was one of the main reasons (simple recipe storage and change of recipes), for choosing the Philips MBC. Another reason was the facility of providing detailed printouts and totalising of material consumption. The MBC is a Microcomputer Batching System with well proven standard software designed for industrial use, and made to be used under industrial conditions, especially in the glass industry, where reliability is important and consistency of the batches is a must. Operation is simple and performed from the keyboard and a mimic panel. The MBC with its Weighing Point Modules and its input and outputs is placed in a panel and does not form part of the operator controls.

Anon. *Bulk Solid Handl* v 8 n 1 Feb 1988 p 65-66.

## Control

**092965 NEW WEIGHING SYSTEMS BY MOTHERWELL CONTROL SYSTEMS LTD.** The Motherwell InFlo Division of Motherwell Control Systems continues to break new ground in the application of continuous weighing systems, as evidenced by some recent contracts which are described. These include: weighing/blending system to a coal washing facility; lorry load-out scheme to speed up load/dispatch operations; belt scale units for trans-shipment terminals. Motherwell is meeting these and other challenging applications such as the new tube conveyor designs, with courage based on its proven experience with world class clients, and is at the same time extending its activities to cover an increasingly comprehensive range of products and services, particularly the control systems associated with weighing installations.

Kelly, John P. (Motherwell Control Systems Ltd, Orpington, Engl). *Bulk Solid Handl* v 8 n 1 Feb 1988 p 59.

**092966 STEVENS CHECKWEIGHER FOR BAKERIES.** Their Average Weight systems have already been installed at nearly 100 bakeries in the U.K. and the latest Model 280 uses microprocessor based electronics designed specifically for the bakery industry. The unit is dust and splash proof sealed to IP65 standards and incorporates a printer to provide all the data recording required by Average Weight Legislation. Information from the printer includes time and shift number, product identification (from a memory of up to 22 individual lines) and weight of each product. The weigh unit provides tare input to delete the packaging weight and an indication of tolerance performance on two levels.

Anon. *Bulk Solid Handl* v 8 n 1 Feb 1988 p 62.

**092967 LOSS-IN-WEIGHT FEEDERS FIT IN TIGHT QUARTERS.** The heart of the Loss-in-Weight Feeder is the time-and-test-proven AccuRate feeder, with its unique agitation features. This feeder rests upon a counterbalanced scale that weighs only the material in the feeder, not the feeder itself, for maximum resolution. The third component is a state-of-the-art control that incorporates a CRT monitor for instant display of functions, commands, current situations and operations. This easy-to-use control displays mode of operation, feeding parameters, operations information, alarm parameters and more.

Anon. *Bulk Solid Handl* v 8 n 1 Feb 1988 p 63.

**092968 ENHANCING THE POWER OF PROCESS WEIGHING.** Weighing ingredients as a method of providing for batch process control, instead of measuring flow or level, has grown in popularity over the last few years, particularly where mixture additions involving solids and powders, or variable density fluids, are concerned. Process weighing for batch monitoring and control has advanced slowly, but now the techniques are broadening their appeal.

Tinham, Brian. *Control Instrum* v 19 n 9 Sep 1987 p 81, 85, 87.

## Control Systems

**092969 MAGNETIC SCALES FOR LINEAR ENCODING.** Experienced control designers know that feedback encoders must be located close to the controlled axis. This practice minimizes error sources that can degrade position measurements and cause problems. However, it is often difficult to get such optimum positioning, particularly when using linear encoders. The glass scales frequently employed in these devices must be kept away from sources of contamination such as smoke, fumes, oil, coolant, or metal chips. One way to avoid such difficulties is to use magnetic scales as feedback encoders. The paper describes how magnetic encoders are a worthwhile alternative to glass scales in harsh conditions where dirt and grime can foul position measuring instruments.

Billingsley, John (Natl Machine Systems Inc, Orange, CA, USA). *Mach Des* v 58 n 28 Nov 20 1986 p 142-145.

**Design** See GRANULAR MATERIALS—Weighing.

## Display Systems

**092970 IMPROVING A SAND BLENDING PROCESS BY CONTINUOUSLY DISPLAYING INGREDIENT WEIGHT AND FLOW RATIOS.** Demand for rigidly specified aggregate products has led to a new system for controlling the manufacturing of blended sand products at Northwest Aggregates Company, USA. A personal computer-based product provides the operator with a continually updated display for adjusting the blending process. During the first month of operation, operators have decreased the Fineness Modulus range to 0.15 for all products and to 0.05 for specific product runs. Additionally, final weight of each of four ingredients typically deviates from target by one percentage point. (Edited author abstract) 4 refs.

Nachtigal, Chester L. (Kistler-Morse Corp, Redmont, WA, USA); Mann, William H.; Inwards, Richard W. *Bulk Solid Handl* v 8 n 2 Apr 1988 p 189-193.

## Electronic

**092971 GERAETEBAU-PROBLEMLÖSUNG FUER EINE SELBSTBEDIENUNGSWAAGE.** [Instrument Engineering Solution for a Self-Service Balance]. The idea of a self-service balance comes from the U.S.A. where for many years now shoppers have been able to preweigh their purchases, especially of fruit and vegetables. Later at the cash-desk the definitive weight and purchase price are established with a check-out balance. It was this idea that gave rise to the wish for a self-service balance as a complete solution for Finland, Sweden and Norway. Finish products were already available on the market, so a solution had to be developed and delivered quickly. A first step was taken with an interim solution consisting of familiar components with certain modifications. This article describes how the self-service balance was developed from the interim solution into a special-purpose product and how it is built up of mechanical, optical, electronic and software components. (Author abstract) In German. 1 ref.

Balingen, Horst Kraft. *F&M Feinwerktech Messtech* v 95 n 6 Sep-Oct 1987 p 353-357.

**092972 ELECTRONIC SCALES: THE BALANCE TIPS TO MORE SYSTEMS.** Computer interfaces from bar code options such as hand-held scanners and label printers to radio telemetry make electronic scales more productive in weighing and counting. As a result, scales now perform more functions and are easily integrated into other handling systems. They produce productivity gains in inventory accuracy, parts kitting, parcel shipment throughput and other areas.

Feare, Tom. *Mod Mater Handl* v 42 n 10 Sep 1987 p 63-66.

**092973 WEIGHT FORWARD.** Improved and cheaper electronics have furthered the development of highly accurate multiple loadcell weighing systems. It is in this area, particularly those applications using lower capacity those applications using lower capacity bending beams, where the single-point or 'center-cell' loadcell has been making progress. The availability of higher capacity single-point designs means that units are no longer restricted to the retail, postal and bench-scale markets. The article describes some available equipment.

Proctor, Andrew. *Process Eng (London)* v 68 n 9 Sep 1987 p 69, 71-72.

**092974 ADVANCEMENT OF LOAD CELL WEIGHING TECHNIQUES FOR HIGH SPEED NETT WEIGHERS WORKING IN HARSH ENVIRONMENTS.** To provide greater control with higher speed and accuracy, a new generation of weighers has been developed, employing a single load cell. Initial designs used a bending beam load cell, and a parallelogram flexure linkage system that catered for uneven loading in the weighpan and eliminated the need for anti-sway links. A design to eliminate side forces but still retain the direct load cell concept has now been achieved by means of a cantilever support system incorporating a single tension load cell. The cell is of unit construction and can be accurately machined and set up on the bench before being inserted into the weigher. The life of the load cell is also extended as the unit has overload protection stops capable of withstanding 500% overload.

Ford, Derek (Richard Simon & Sons Ltd, Nottingham, Engl); Smith, David. *Bulk Solid Handl* v 8 n 1 Feb 1988 p 43-46.

**092975 ELECTRONIC BELT WEIGHERS FOR RUMANIAN BEET SUGAR INDUSTRY.** Electronic Belt Weighers Series 1200 supplied by Adequate Services were chosen and installed by the Rumanian Beet Sugar Industry to improve the monitoring of product and consequential efficiency of sugar extraction. The machines are now in their factories providing precise measurement of throughput and control of the extraction process. The machines give digital readout of Total Weight. Flow Rate in tons per hour and kilograms per metre, with computer compatible signals. Also a comprehensive diagnostic programme monitoring both weigher and conveyor performance.

Anon. *Bulk Solid Handl* v 8 n 1 Feb 1988 p 62.

**092976 HIGHLY ACCURATE LOAD CELL FOR USE IN HOSTILE ENVIRONMENTS.** A compact bending beam load cell that combines high accuracy with a water proof, stainless steel package has been introduced. Designated the SHB, the new load cell is available for quantity dry batch or liquid weighing applications in hostile environments, including industrial floor scales, tank and hopper scales, and filling machines. The SHB is rated by the West German PTB at the high accuracy level of C3 (3000 Divisions) for use in Class III scales.

Anon. *Bulk Solid Handl* v 8 n 1 Feb 1988 p 64.

**092977 OPTICAL LOAD CELL TRANSDUCER.** The technology produces a very low profile, low physical weight load cell with no temperature or hysteresis effect. An 8,000 kg transducer is 50 mm<sup>2</sup> by approximately 12 mm thick and only grams in weight. The intensity of the output beam is determined by a Pin Diode, which converts light intensity to voltage in an opamp feed back arrange-

ment. With the Pin Diode in reverse bias the diode leakage current is linearly dependent on light and the output voltage is also a linear function of the light intensity.

Anon. *Bulk Solid Handl* v 8 n 1 Feb 1988 p 65.

**092978 PROCESS WEIGHING EQUIPMENT.** Negretti Automation manufactures a wide range of load cells and associated measuring and control instrumentation designed to meet the requirement of industrial weighing processes. Prominent among these is a range of Shear Beam Load Cells for compressive and tensile loads. The Digital Weightfinder is available on a 3½ or 4½ digit indication and has two fully adjustable trip points. The unit is ideal for precision low cost weight indication and control applications. The Weightcontroller is a versatile instrument available as either a precision weight indicator with 8 operator adjustable trip points or as a batch controller with 10 protected pre-set recipes. The MPC84 is a programmable process controller that accepts direct load cell input as well as other analogue and digital process I/O.

Anon. *Bulk Solid Handl* v 8 n 1 Feb 1988 p 68.

**092979 NEW LOAD CELLS FROM HUNTLEIGH TECHNOLOGY.** The HSB load cell, a new low profile shearbeam load cell, is now available in a stainless steel version with a capacity up to 5 tons. It is designed for single and multiple heavy industrial and process weighing applications where environmental conditions could be harmful to the standard steel bodied cell. The DC6 load cell is available in capacities ranging from 20 kg to 200 kg with the same accuracy specification as given above. The load cell is hermetically sealed to protect its strain gauge and internal circuitry and of low profile.

Anon. *Bulk Solid Handl* v 8 n 1 Feb 1988 p 66.

**092980 BELT SCALE TECHNOLOGY UTILIZES PARALLELOGRAM PRINCIPLE.** Millitronics has developed a single idler belt scale which gives instantaneous readings to variations in product loading. This innovation has been achieved with the use of a floating suspension consisting of two load cells. Utilizing the parallelogram principle, the load cells react only to the vertical force of the mass transmitted through the weighing idler, and never to idler friction, sideforces and off-center loading. As a consequence of the patent-protected design, the Millitronics single idler belt scale (MSI) provides greater than usual accuracy for standard single idler cost. It has proven reliable on previously inappropriate single idler scale applications, such as those with faster moving belts and uneven loading.

Closs, Ralph (Millitronics, Peterborough, Ont, Can). *Bulk Solid Handl* v 8 n 2 Apr 1988 p 194.

**092981 WEIGHTING UNITS CONTROL MATERIAL AND PROCESSES.** Electromechanical scales, which have been integrated into material flow, are now an important element for quality control, optimization, control and regulation, classification, marking, invoicing, maintaining ledgers for materials and costs. They must be able to be configured in compact or decentralized form, and to be integrated into or adapted to other systems. This involves the development of evaluation and display equipment such as terminals/monitors and software for standardized modules, supplemented by tasks specified by users. Examples of application, taken from a variety of process-engineering fields, demonstrate the variability and the ability of weighing systems to be adapted to and integrated into automated production processes with the ability to be partially standardized for data recording and processing. (Edited author abstract). 3 Refs.

## Errors

**092982 CALCULATION AND MINIMIZATION OF THE ERROR OF BEAM BALANCES CAUSED BY NONPARALLELISM OF THE KNIFE-EDGES.** Nonparallelism of the working edges of the input and

output knife-edges of the weighing beam relative to the working edge of the bearing knife-edge is a source of error in balances. The qualitative aspect of this phenomenon was discovered and separate elements of the theory have been presented. In this paper the authors analyze the error due to nonparallelism of the working edges for a beam mechanism of a general type with the basic factors taken into account. 4 refs.

Ishkhanov, I.A. *Meas Tech* v 30 n 6 Jun 1987 p 523-526.

**092983 ACCURACY AND SPEED OF INTRACYCLIC ALGORITHMS FOR WEIGHT-SPACE DISPENSING.** Weight-space methods (WSM) of dispensing are being increasingly used for constructing high-accuracy dispensers of small masses of bulk materials. Different algorithms for WSM, in particular, intracyclic algorithms, in which the dose formed is divided into a series of sequential subdoses, whose masses are measured and subsequent subdoses are formed from the results of these measurements, are used to reduce measurement error. The fact that an analysis of the accuracy and speed of such algorithms is not contained in the literature prevents evaluating their applicability when the dispensers are being designed. In this paper the authors attempt to fill this omission. 6 refs.

Polunov, Yu.L. *Meas Tech* v 30 n 6 Jun 1987 p 527-529.

**Industrial Applications See IRON AND STEEL PLANTS—Measurements.**

## Magnetic

**092984 NOVEL WEIGHING METHOD USING MAGNETIC COUPLING OF BALANCE AND SAMPLE BY A PERMANENT MAGNET.** A weighing method is described which uses coupling of an electromagnetic balance and the sample with permanent magnets. One magnet is fixed to the balance and attracts a second induced or permanent counter magnet which is attached to the sample and can move freely between two supports in a sealed nonferromagnetic sample cell. At the critical floating distance  $r_c$  of the two magnets, the effective mass  $m(r_c)$  indicated by the balance is equal to the desired apparent mass  $m$  of the counter magnet. This unstable state of mass equality can be observed precisely by the balance itself, because the counter magnet moves from its support and either rises or falls very rapidly to the other support. The result of these events is an effective mass change from  $m(r_c)$  to  $m(r_c \pm d)$  indicated by the balance (where  $d$  is the distance moved by the counter magnet). (Edited author abstract) 14 refs.

**Precision Balances See ALSO FLOW OF FLUIDS—Channel Flow; PLASTICS FILMS; SEMICONDUCTING SILICON—Mechanical Properties.**

**092985 METHOD OF DETERMINING THE INSTRUMENTAL ERROR IN A REMOTE-READING SYSTEM FOR TAKING READINGS FROM A PRECISION BALANCE.** Tests have been made during metrological certification on precision balances which showed that deviation in any element of the readout system (RS) from the optimum position produced a component in the instrumental error. The most difficult task in measurement accuracy estimation is observing the error components; one tends to eliminate factors that cause them or to reduce the effects to a minimum by adjustment. For this purpose, we propose a method of determining the instrumental error component arising from mismatch between the RS components. 3 refs.

Afanas'ev, S.N.; Biryuzov, S.V. *Meas Tech* v 30 n 2 Feb 1987 p 135-137.

**092986 ESTIMATING THE METROLOGICAL CHARACTERISTICS OF PRECISION BALANCES.** The balance consists of the following systems: for taking the readings (automatic and visual), for weighing proper,

for remote control, and for processing the data. The weighing system proper is used in balancing the measures in transferring the unit of mass. The automatic reading system (RS) produces an electrical signal proportional to the limiting deviation  $\epsilon_1$  of the pointer from the zero position. The balance were tested by a special method that took account of their design features. We determined the value of a scale division and the standard deviation SD in the observations with automatic and visual readout. The calculations were made from results on comparing two weights A and B of mass 1 kg each. These studies showed that the RS scale division remains virtually unaltered during a single observation period (about two weeks), so it should be determined once before or after the comparison of the weights. The results also show that automating the readings reduced the RS scale division by a factor 4-5. 3 refs.

Afanas'ev, S.N.; Biryuzov, S.V.; Malysheva, T.A.; Pavlov, I.V.; Sidel'nikov, A.I. *Meas Tech* v 29 n 2 Feb 1986 p 88-90.

**092987 EASY-TO-BUILD BALANCE FOR AUTOMATIC MEASUREMENT.** The design and construction of a continuously recording precision balance resistant to varying pressure and temperature conditions and suitable for data acquisition systems is described. A horizontal beam is suspended at both ends by a pair of wires yielding a trapezoidal configuration. The horizontal displacement of the beam due to the difference of a probe mass acting on one beam end compared with a reference mass attached to the other end is tracked by an inductive displacement transducer. The prototype achieved an overall accuracy better than 50 mg in the range 30-50 g at temperatures ranging from 20 to 100°C. The temperature coefficient of the offset was found to be initially 10 mg K<sup>-1</sup> and was reduced to a total residual error of 50 mg over the entire range by temperature compensation. (Edited author abstract) 4 refs.

## Process Control

**092988 PROCESS WEIGHT INDICATOR COMMUNICATES ON DATA NETWORK.** Kistler-Morse introduces the 1020 Weight Indicator, which displays the weight of material stored in bins, tanks, silos, and other industrial vessels, on a bright digital readout. An RS422 serial interface allows networking of many indicators with process control computers or management data files. The 1020 is compatible for use with most PCs and serial input printers. Net and gross weight displays, push-button tare, programmable setpoints, isolated current transmitter, and many other advanced features offer tremendous versatility. The rugged NEMA-4 enclosure and unique sensor design ensure years of reliable operation, even in harsh process environments.

## Reliability

**092989 DERZEITIGE GENAUIGKEITSGRENZEN BEI 1-KG-KOMPARATORWAAGEN.** [Historical Accuracy Limits of 1 Kg Comparator Scales]. By means of the most accurate prototype balances (beam scales with knife-edges and pans) the quantities influencing the scale, the mass standard and the weighing are described. The resulting requirements for the improvement of the relative standard deviation to  $s_{rel} < 5 \cdot 10^{-10}$  have led to three new developments: balance according to the principle of electrodynamic force compensation; beam scale with flexure strip suspensions; balance according to the hydrostatic weighing principle. The measuring principles are presented and the results hitherto obtained described. (Author abstract) 11 refs.

Kochsiek, M. *PTB Mitt* v 97 n 3 Jun 1987 p 179-186.

## Stability

**092990 STABILITY ANALYSIS OF THE ELECTRONIC BALANCE BY ROOT-LOCUS TECHNIQUE.** In this study a TG 528B damping analysis balance is reformed into an electronic balance with LED digital display. The stability analysis of the electronic balance is conducted by root-locus technique and put into practice with satisfaction. The maximum capacity, sensitivity, linearity and stable time of the electronic balance reaches up to 199.9 g, 0.001 g, 0.05% and 0.5 second, respectively. (Author abstract) In Chinese. 6 refs.

Xu Guohua. *Huadong Huagong Xueyuan Xuebao* v 14 n 1 1988 p 121-126.

## Standards

**092991 PORTABLE AUTOMATED, INEXPENSIVE MASS AND BALANCE CALIBRATION SYSTEM.** Reliable mass measurements are essential for a nuclear production facility or process control laboratory. DOE Order 5630.2 requires that traceable standards be used to calibrate and monitor equipment used for nuclear material measurements. To ensure the reliability of mass measurements and to comply with DOE traceability requirements, a portable, automated mass and balance calibration system is used at the Savannah River Plant. Automation is achieved using an EPSON HX-20 notebook computer, which can be operated via RS232C interfacing to electronic balances or function with manual data entry if computer interfacing is not feasible. This economical, comprehensive, user-friendly system has three main functions in a mass measurement control program (MMCP): balance certification, calibration of mass standards, and daily measurement of traceable standards. The balance certification program tests for accuracy, precision, sensitivity, linearity, and cornerloading versus specific requirements. The mass calibration program allows rapid calibration of inexpensive mass standards traceable to certified Class S standards. (Edited author abstract)

## Weigh Stations

**092992 NEW WEIGHING CONCEPT ENABLES ACCURATE INVENTORY CONTROL IN CONTINUOUS MATERIAL THROUGHPUT APPLICATIONS WITH HIGH ACCURACY STATIC WEIGHING.** A trend in today's marketplace is to use high accuracy static scale systems in continuous material flow operations. This trend is due to an increased awareness and understanding of the economic advantages of using systems which provide high weighing accuracy. Front end costs are substantially higher than such systems as conveyor belt scales, but many operations are looking further ahead in their weighing systems selection than the initial system cost. System paybacks and return on investment concerns have proven that the economic advantages of static weighing systems may well be justifiable. Again, the main concern in weighing a product with the highest degree of accuracy is not just to know how much material came into or went out of an operation, but to obtain the greatest control. Gaining this control of product gives you the control of your money. (Edited author abstract)

## SCANDIUM AND ALLOYS

### Analysis

**092993 STUDY ON THE DETERMINATION OF RE IN SCANDIUM OXIDE USING THE DUAL-SYSTEM AND DOUBLE-WAVELENGTH METHOD.** The dual system and double wavelength spectrophotometry has been applied to the determination of RE impurities in scandium oxide. The procedure is accomplished as follows: Select 682 nm, the absorbance maximum of RE-CPA-PI absorption spectrum, as the analytical wavelength. Determine 596 nm (or 614.5 nm) on the Sc-CAS absorption spectrum by the isosbestic points method as the reference wavelength. (Edited author abstract) In Chinese. 5 refs.

Lin, Jin-he (Nankai Univ, China); Han, Chao; Shi, Hui-ming. *Xi You Jin Shu* v 6 n 3 Aug 1987 p 217-221.

## Oxidation

**092994 INVESTIGATION OF AIR-GROWN SCANDIUM OXIDE AND EXPERIMENTAL DETERMINATION OF THE INELASTIC MEAN-FREE-PATH IN SCANDIUM AND IN SCANDIUM OXIDE.** The thickness of the passivation layers formed in air on scandium at room temperature was measured by XPS, using the inelastic mean-free-path (IMFP) of the Sc 2p photoelectrons as well as an extrapolation of layer-thickness measurements at oxygen exposures  $\leq 10^6$  L. The IMFP of scandium and scandium oxide was determined experimentally by the 'overlayer' technique. The XPS standard spectra of metallic scandium and of scandium oxide were recorded. The line parameters of the Sc 2p and of the O 1s spectra were determined by a convolution program. (Author abstract) 20 refs.

Reichl, R. (Univ of Tuebingen, West Ger); Gaukler, K.H. *Appl Surf Sci* (1985) v 31 n 4 May 1988 p 460-470.

**092995 STUDIES OF THE OXIDATION OF SCANDIUM AND YTTRIUM USING THERMOGRAVIMETRY AND ELLIPSOmetry.** High-temperature air oxidation of powder and compact specimens of Y and Sc was studied. Values of the effective activation energy of the oxidation process were measured. It is shown that the kinetic curves for Y oxidation under isothermal conditions have an inflection related to oxygen dissolution in the metal matrix. 11 refs.

## Photochemical Reactions

**092996 STUDY OF THE EFFECT OF SOLVATION, MIXED MICELLA AND NEGATIVE ION ON THE COLOUR REACTION OF Sc-CAS SYSTEM.** In this paper the effect of solvation, mixed micella and negative ion on the colour reaction of the Sc-CAS-CTMAB system has been investigated. Experimental results show that the addition of ethyl alcohol, emulsifier OP or negative nitrogen ion has a similar effect on photochemical properties. These additions speed up the reaction rate, improve operating conditions and enlarge the workable range of pH values. The authors also determined the effect of more than twenty materials on the microanalysis of Sc. (Edited author abstract) 12 refs. In Chinese.

Zhang Gui-zhu (Nankai Univ, China); Shi Hui-ming. *Xi You Jin Shu* v 5 n 2 May 1986 p 114-121.

## Processing

**092997 INVESTIGATIONS IN THE SCANDIUM-NITROGEN SYSTEM.** Single-phase samples of  $\delta$ -ScN<sub>1-x</sub> and two-phase Sc/ScN alloys were prepared by direct nitridation of Sc metal and by arc-melting of ScN + Sc, respectively. The lattice parameters of  $\delta$ -ScN<sub>1-x</sub> prepared at 1370-1770 K were measured. Microprobe Sc profiles across diffusion layers of  $\delta$ -ScN<sub>1-x</sub> on Sc metal prepared at 1380 and 1770 K indicate that in this temperature range ScN<sub>1-x</sub> has a homogeneity range of ScN<sub>0.87</sub>-ScN<sub>1.00</sub>. In the diffusion 1 the dark blue color of ScN on the nitrogen-rich surface takes on a clearly visible violet tinge near the Sc/ScN boundary. Nitridation of solid Sc metal results in a porous or hollow nitride sample. This is probably due to the preferential diffusion of Sc<sup>3+</sup> ions through the originally formed ScN layer. (Edited author abstract). 9 refs.

## Solvent Extraction

**092998 SOLVENT EXTRACTION OF SCANDIUM FROM WOLFRAMITE RESIDUE.** The particular properties of scandium make it an attractive candidate for recovery by solvent extraction - one of the most important processes in hydrometallurgy for the separation, purification and concentration of metal ions. Toward this end, an acid leaching and solvent extraction system has been developed and optimized to extract scandium from wolframite residue. With the technique, the scandium oxide content in the resultant scandium hydroxide can reach 70-78 percent. Further, the concentration coefficient and total recovery of scandium oxide from the residue to the product has amounted to  $(1.9-3.9) \times 10^3$  and 76-89 percent, respectively. (Edited author abstract). 4 refs.

## Specific Heat

**092999 SPECIFIC HEAT MEASUREMENTS IN SCANDIUM-RARE EARTH ANISOTROPIC SPIN GLASSES.** We report on specific heat measurements at low temperatures of the anisotropic spin glass alloys ScDy 3 at%, ScEr 4.25 at% and ScEr 10 at%. We find that at the lowest temperature range the data indicate the occurrence of an anisotropy induced gap around zero frequency in the density of states of the magnetic excitations. Moreover, some of our specific heat curves present a maximum coinciding with  $T_g$ , raising thus the question of thermal signs for a spin glass phase transition in anisotropic systems. (Author abstract) 21 refs.

## SCANDIUM COMPOUNDS

### Physical Properties

**093000 INTERBAND TRANSITIONS IN ScPd<sub>3</sub> AND YPd<sub>3</sub>.** A theoretical ab-initio study of optical properties of ScPd<sub>3</sub> and YPd<sub>3</sub> is presented. Agreement with experimental data for YPd<sub>3</sub> in the high energy range is excellent. In the low energy range a sharp narrow peak in YPd<sub>3</sub> is obtained which is not observed experimentally due to Drude's correction. In the case of ScPd<sub>3</sub> this low energy is shifted somewhat towards higher energy and it is very intense, hence more probable to be observed. (Edited author abstract) 12 refs.

**093002 ROUTING AND SCHEDULING OF WARDENS FOR PUBLIC CAR PARK INSPECTION.** This paper presents a case study on the inspection operations of public car parks which employ a 'coupon parking' system with checking by wardens. The problem is to determine an optimal staffing level for the wardens as well as an optimal schedule for their deployment. A framework is laid out in the paper for modeling the car park inspection policy, and some heuristic procedures are developed for the determination of number of wardens required in a zone. The proposed model has been tested against some field data, leading to results that provide a more rational and systematic basis for the scheduling of inspection operations. (Author abstract) 4 refs.

**093003 FINITE SCHEDULING: IT WORKS IF... SCHEDULING JOBS AND MACHINES TO MEET CUSTOMER DELIVERY DATES IS MORE SCIENCE THAN ART AND IS PRONE TO FAILURE.** Computer-based scheduling systems are only marginally successful. There are many reasons why some finite-scheduling approaches have not worked in make-to-order job-shop manufacturing operations. One primary reason is because it lacks a machine-job sequencing function. Sequencing places operations on machines in a chronological time-sequence, along with the operations from thousands of other jobs competing for the same machine resources. Not only is it necessary to come up with a sequence for each machine, but those sequences must be coordinated so that operations from each job can move feasibly from one machine to another, and, at the same time, be sure that the jobs are completed by their respective due dates or delivery schedules.

Connor, Jon L. (Heuristica Corp, Seattle, WA, USA). *Manuf Syst* v 5 n 8 Aug 1987 p 39-40.

**093004 MULTI-JOB CYCLIC SCHEDULING FOR AN AUTOMATED FLOW-TYPE MANUFACTURING SYSTEM (RELATIONSHIP BETWEEN JOB OUTPUT INTERVAL AND BUFFER CAPACITY).** A multi-job cyclic scheduling problem for an automated flow-type manufacturing system was analyzed. Flow of jobs in the system was represented as a network. Using the network representation, the job output interval in a steady state was obtained. In the cyclic scheduling problem, an optimum schedule is a non-idle schedule, where a bottleneck machine produces jobs without idle time in a steady state. A lower bound on the buffer capacity and a scheduling method were obtained to construct a non-idle schedule. (Author abstract) In Japanese. 7 refs.

Yura, Kenji. *Nippon Kikai Gakkai Ronbunshu C Hen* v 53 n 493 Sep 1987 p 2054-2059.

**093005 OPTIMAL TOTAL-WORK-CONTENT-POWER DUE-DATE DETERMINATION AND SEQUENCING.** This paper considers sequencing of  $n$  jobs on a single machine. The total-work-content-power (TWK-P) due-date assignment method is used to assign due-dates to jobs. The objective is to determine the optimal due-date multiple factor so as to minimize a cost function based on the due-date multiple and job earliness, and tardiness values. A linear programming (LP) formulation of the problem is proposed and the optimal solution is determined via considering the LP dual problem.

Cheng, T.C.E. (Univ of Manitoba, Winnipeg, Manit, Can). *Comput Math Appl* v 14 n 8 1987 p 579-582.

**093006 EVALUATING PROJECT SCHEDULING AND DUE DATE ASSIGNMENT PROCEDURES: AN EXPERIMENTAL ANALYSIS.** This study presents a number of important results for managers interested in scheduling projects and setting due dates. First, using more information concerning the current work in progress, available resources, and activity precedent relationships provides a better due date estimate for a new project. Second, a finite scheduling procedure (called SFT) consistently gives better due date estimates than simpler aggregate procedures. Third, when some project due dates are set externally, due date performance deteriorates. Fourth, the effort, measured by CPU time, for SFT to estimate a good due date depends upon the ratio of activity resources required to total resources available, rather than the number of activities across all projects. And fifth, similarities and differences between the results observed in this study and past due date job shop scheduling research are reviewed. (Edited author abstract) 30 refs.

**093007 SUITABILITY OF THE WEIGHTED  $l_p$ -NORM IN ESTIMATING ACTUAL ROAD DISTANCES.** This paper evaluates whether, on the basis of easy-to-obtain data characterizing the road network of a particular area, one can predict the extent of the improvement in estimate accuracy. Such an ability to predetermine estimate accuracy would help researchers decide when to use the expensive  $l_p$ -norm. The investigation shows, however, that no such relationship can be proven. The extent of the improvement in estimate accuracy offered by the weighted  $l_p$ -norm cannot be predicted. (Edited author abstract) 12 refs.

Berens, Wolfgang (Univ Muenster, Muenster, West Ger). *Eur J Oper Res* v 34 n 1 Feb 1988 p 39-43.

**093008 TWO-MACHINE FLOW SHOP SCHEDULING PROBLEM WITH CONTROLLABLE JOB PROCESSING TIMES.** The paper deals with a two-machine flow shop scheduling problem in which both the sequence of jobs and their processing times are decision variables. It is assumed that the cost of performing a job is a linear function of its processing time, and the schedule cost to be minimized is the total processing cost plus maximum completion time cost. It is shown that the decision form of this problem is NP-complete, even when the processing times on one machine only are controllable and all the processing cost units are identical. Two heuristic methods for solving the problem are proposed and their worst-case analysis is presented. (Author abstract) 8 refs.

**093009 SINGLE MACHINE SCHEDULING TO MINIMIZE WEIGHTED EARLINES SUBJECT TO NO TARDY JOBS.** This paper considers the single machine scheduling problem where the objective is to minimize the total weighted earliness subject to no tardy jobs. Known results for a well researched single machine scheduling problem where the objective is to minimize the weighted completion time subject to no tardy jobs have been used in analyzing this problem. Several important results are proved and both exact and approximate methods are developed to solve this problem. (Author abstract) 10 refs.

**093010 HEURISTIC SCHEDULING POLICY FOR MULTI-ITEM, SINGLE-MACHINE PRODUCTION SYSTEMS WITH TIME-VARYING, STOCHASTIC DEMANDS.** A heuristic scheduling policy is introduced for multi-item, single-machine production systems facing stochastic, time-varying demands. The policy, which we term the dynamic cycle lengths heuristic, integrates feedback control based on the monitoring of inventory levels with the maintenance of economic production cycles. The policy is applied time period by time period to make decisions concerning which items to produce in what quantities during the next time period. (Edited author abstract) 17 refs.

**093011 SHIFTING BOTTLENECK PROCEDURE FOR JOB SHOP SCHEDULING.** We describe an approximation method for solving the minimum makespan problem of job shop scheduling. It sequences the machines one by one, successively, taking each time the machine identified as a bottleneck among the machines not yet sequenced. Every time after a new machine is sequenced, all previously established sequences are locally reoptimized. Both the bottleneck identification and the local reoptimization procedures are based on repeatedly solving certain one-machine scheduling problems. Besides this straight version of the Shifting Bottleneck Procedure, we have also implemented a version that applies the procedure to the nodes of a partial search tree. Computational testing shows that our approach yields consistently better results than other procedures discussed in the literature. (Edited author abstract) 13 refs.

**093012 SIMULATION STUDY OF JOB SHOP SCHEDULING WITH DUE DATES.** This paper presents a study of a hypothetical job shop by computer simulation. The purpose is to investigate the main and interaction effects of three shop decision variables: (a) the job dispatching rule, (b) the due-date assignment method, and (c) the shopload ratio, on a shop performance measure defined as the percentage of jobs late. The multiple regression analysis technique is employed to estimate the functional relationship between the performance measure and shop decision variables. Two potential applications of the regression model are explored and discussed. (Author abstract) 10 refs.

**093013 PROJECT SCHEDULING WITH MULTIPLE, DOUBLY CONSTRAINED RESOURCES.** This paper deals with a project scheduling problem in which project activities can be divided into mutually disjoint subsets of those activities which require the same resource. Mathematical models of activities are given in the form of performing speed - resource amount functions and binary conditions imposed on initial and final states of activities. The problem of finding optimal resource allocation is stated as an optimal control problem and then transformed into nonlinear programming problem, for which we propose a special computational procedure based on Wolfe's generalized linear programming method. We also present necessary and sufficient conditions for the existence of an optimal resource allocation. (Edited author abstract) 15 refs.

**093014 ON THE INTEGER PROPERTIES OF SCHEDULING SET PARTITIONING MODELS.** The approach discussed in this paper not only reduces the size of the feasible region by reducing the number of valid variables, but also lessens the potential for fractionality. We impose additional problem structure not already implicit in the mathematical model. This structure ensures

that many of the basic feasible solutions of the reduced LP are integer, or near-integer in the sense that fractional values can easily be resolved. In this paper, we discuss the theoretical basis for the natural integer properties of the reduced set partitioning linear program. 24 refs.

**093015 ONE-PROCESSOR SCHEDULING WITH SYMMETRIC EARLINESS AND TARDINESS PENALTIES.** We consider one-processor scheduling problems having the following form: Tasks  $T_1, T_2, \dots, T_N$  are given, with each  $T_i$  having a specified length  $l_i$  and a preferred starting time  $a_i$  (or, equivalently, a preferred completion time  $b_i$ ). The tasks are to be scheduled nonpreemptively (i.e., a task cannot be split) on a single processor to begin as close to their preferred starting times as possible. We examine two different cost measures for such schedules. For the first of these, we show that the problem of finding minimum cost schedules is NP-complete; however, we give an efficient algorithm that finds minimum cost schedules whenever the tasks either all have the same length or are required to be executed in a given fixed sequence. For the second cost measure, we give an efficient algorithm that finds minimum cost schedules in general, with no constraints on the ordering or lengths of the task. (Edited author abstract) 12 refs.

**093016 MORE EFFICIENT FORMULATION OF THE SINGLE MACHINE, STATIC DEMAND, LOT SCHEDULING PROBLEM.** The classical assumptions of the economic lot scheduling problem have two main drawbacks. They lead to false cost calculations and the solutions developed under them are often difficult to implement. In this paper, more realistic assumptions are suggested and it is shown that these new assumptions allow a more efficient formulation of the problem. The characteristics of this formulation are studied and it is shown that, for a given production sequence, the model reduces to a continuous linear program with a totally unimodular constraint matrix. **093018 OPTIMAL CONSTANT DUE-DATE ASSIGNMENT AND SEQUENCING.** The paper considers the sequencing of  $n$  jobs in a single-machine shop in which each job is assigned a constant flow allowance. The objective is to determine the optimal value of the flow allowance and the optimal job sequence to minimize a cost function based on the flow allowance and the job earliness and tardiness values. We first propose a linear programming (LP) formulation of the problem. We then derive that it is independent of the job sequence. After the theoretical treatment, a numerical example is presented for discussion. (Author abstract). 9 Refs.

**093020 TOWARDS THE STANDARDIZATION OF PERFORMANCE MEASURES FOR PROJECT SCHEDULING HEURISTICS.** Performance measures that can be used to compare project-scheduling heuristics are presented. Quantitative measures relative to the project duration are proposed for the diagnostic analysis of activity-sequencing heuristics in PERT networks with precedence and resource constraints. The aim is to establish a basis for the standardization of performance measures for the heuristics. A project analyst can use the evaluation techniques presented in deciding which of the many available scheduling heuristics is most appropriate for a given project scenario. A comparative experiment indicates that heuristics perform almost equally well for small projects, while their performances vary considerably for large projects. Thus, small projects with mediocre complexity are not accurate performance-measurement agents for scheduling heuristics. 27 refs.

**093021 INORGA SCHEDULING SYSTEM.** Many systems have been developed for the scheduling of piece and small batch production, one of them at Inorga Institute in Prague. This system consists of three relatively independent levels, each of which can be used separately. The orders for final products are planned in Rough Scheduling, which represents the highest level in our scheduling hierarchy. The most important condition for a feasible schedule is to accept all due-dates, the optimality criterion is to minimize differences between capacity needs and requirements for all products, capacities and time periods. A similar approach is used for the lower scheduling level, i.e. for Fine Scheduling. Batches of parts are planned here for groups of machines on workshop levels. The lowest scheduling level, Dynamic Rescheduling, is concerned with single machines and single operations. (Edited author abstract) 3 refs.

**093022 SIMPLE AND INTEGRATED HEURISTIC ALGORITHMS FOR SCHEDULING TASKS WITH TIME AND RESOURCE CONSTRAINTS.** We consider the problem of scheduling a set of  $n$  tasks in a system having  $r$  resources. Each task has an arbitrary, but known, processing time and a deadline, and may request use of a number of resources. A resource can be used either in shared mode or exclusive mode. In this article, we study algorithms used for determining whether or not a set of tasks is schedulable in such a system, and if so, determining a schedule for it. This scheduling problem is known to be NP-complete and hence we methodically study a set of heuristics that can be used by such an algorithm. Due to the complexity of the problem, simple heuristics do not perform satisfactorily. However, an algorithm that uses

combinations of these simple heuristics works very well compared to an optimal algorithm that takes exponential time complexity. For the combination that performs the best, we also determine the scheduling costs as a function of the size of the task set scheduled. (Author abstract) 14 refs.

**093024 COMPUTERIZED SHOP FLOOR SCHEDULING.** Computerized shop floor scheduling is probably one of the most glaring examples of an area in which the tremendous efforts and investments of a large number of companies have produced at best only a partial solution. One of the more successful attempts is known as OPT<sup>®</sup> (optimized production technology). This article describes its evolutionary process from basically a computerized Kanban to an attempted computerization of the Drum-Buffer-Rope technique. The major emphasis will be on the reasoning - gained from the experience of implementing this package - that brought this evolution so quickly to its ultimate conclusion. The real key lies mainly in the conceptual framework under which we run our organizations. (Edited author abstract) 11 refs.

**093025 LOOKAHEAD HEURISTIC FOR MULTI-ITEM SINGLE MACHINE PRODUCTION SCHEDULING WITH DYNAMIC, STOCHASTIC DEMANDS.** This paper presents a simple heuristic for scheduling the production of many items on a single machine when demands are both dynamic and stochastic. The heuristic is based on (s,S) type policies and relies principally on simulations of the upcoming production days (the Lookahead function) to decide if the production facility should be shut down or not on a given working shift. Comparative simulation test results show that, under varying production conditions, the Lookahead heuristic provides low total inventory and changeover costs while maintaining high service level. **093027 THROUGHPUT TIME CONTROL.** Accelerating rates of change in product design and process technologies, coupled with more rapid market fluctuations and shorter product life cycles have spelled doom for many manufacturing companies unable to react promptly. A principal fallacy limiting the success of many companies, even those with fine modern computer-based planning and control systems, has been the strong belief that such systems can work well with any lead times. This paper presents the beneficial effects of better control (meaning reduction) of throughput times in all phases of planning, execution and control of manufacturing and shows how well-run companies are achieving such reductions. **093033 ON THE SUPERIORITY OF A BACKWARD APPROACH IN LIST SCHEDULING ALGORITHMS FOR MULTI-MACHINE MAKESPAN PROBLEMS.** List scheduling algorithms are commonly used for the makespan problems of job shops and of identical processors with precedence constraints. These algorithms list operations in some order and then assign them in this order to the machines as they become available. Existing list scheduling algorithms schedule the operations forward. We suggest and test a backward approach, in which the operations are scheduled backward. When the precedence constraints are in-tree like, i.e., when each operation has at most one immediate successor, the backward approach gives better solutions than the forward approach. (Edited author abstract) 16 refs.

**093034 EFFECTS OF SETUP TIME ON OUTPUT CAPACITY IN CELLULAR MANUFACTURING.** When the average setup time is shorter, machines are available for processing relatively more time, leading to an increase in shop output capacity. In this simulation experiment, setup times are lowered, both by implementation family grouping and through the use of a sequence dependent setup time based scheduling procedure. The results clearly showed that reduced setup times led to greater output capacity. The higher input rate in the models with increased capacity, however, had a detrimental effect on many other performance variables in the shop. Some of this detrimental effect was alleviated by the use of a scheduling procedure which was designed to capitalize on the sequence dependent nature of setup times. (Edited author abstract) 28 refs.

**093037 ECONOMIC LOT-SCHEDULING PROBLEM: ACHIEVING FEASIBILITY USING TIME-VARYING LOT SIZES.** This paper considers the Economic Lot Scheduling Problem; that is, the problem of scheduling several products on a single facility so as to minimize holding and setup costs. We develop a formulation that provides feasible schedules by allowing the lot sizes and thus the cycle times for each product to vary over time and by explicitly taking into account setup times. Our main results characterize when feasible schedules exist, quantify the insensitivity of the schedules; costs to minor adjustments, and thus show how close the schedules will be to ones with optimal equal cycle times. We also present a heuristic for finding good feasible schedules. (Author abstract) 30 refs.

**093038 QUASI ON-LINE SCHEDULING PROCEDURES FOR FLEXIBLE MANUFACTURING SYSTEMS.** This paper presents three quasi on-line scheduling procedures for flexible manufacturing systems (FMSs) consisting of work stations, transport devices, and operators. In the scheduling, different types of decisions are taken to perform a particular operation, i.e. the selection of a work station, a transport device and an operator. Further, the scheduling sequence of the operations has to be determined. The three developed procedures differ in the way these four decision problems are solved hierarchically. Several dispatching rules (SPT, SPT/TOT, SPT/TOT and EFTA) are available to solve the last mentioned decision problem. The scheduling procedures involve a buffer handling method to avoid deadlock. Based on simulation tests, some conclusions are drawn about the performance of the scheduling procedures and the various dispatching rules. (Edited author abstract) 8 refs.

**093039 MODEL FOR LOT SIZING AND SEQUENCING IN PROCESS INDUSTRIES.** This paper presents a mixed integer linear programming model for scheduling production in process industries that embodies the economic trade-offs encompassed in three avenues of research: capacitated lot sizing, flowshop scheduling and sequencing with sequence-dependent setup times. The model is used to schedule production for a problem representative of those found in the food processing industry. The corresponding schedule is then compared with approaches that consider lot sizing and sequencing as independent decisions and it is shown that decomposing the scheduling problem into smaller subproblems can result in the generation of infeasible production schedules. (Edited author abstract) 42 refs.

**093043 PLANNING AND SCHEDULING FOR EPITAXIAL WAFER PRODUCTION FACILITIES.** We propose and test several heuristics for scheduling jobs in a multiproduct parallel reactor (machine) shop with different criteria. We introduce a set of indices to measure the degree of homogeneity in the product set. Based on the results of the computational experiments, we recommend that the choice of the heuristic should be guided by the homogeneity of the product set and the chosen objective criterion. We examine two variants of the planning model and briefly comment on their application to the design and layout of the facility. Since one of the variants of the problem is difficult to solve, we present a method to obtain an approximate solution. We provide bounds on the performance of this approximate solution and demonstrate that it is asymptotically optimal. (Edited author abstract) 19 refs.

**093044 DYNAMIC PROGRAMMING SOLUTION TO THE DYNAMIC, MULTI-ITEM, SINGLE-MACHINE SCHEDULING PROBLEM.** Our algorithm, which we developed using an approach similar to C.R. Glassey's that minimizes the total number of changeovers, casts the optimal schedule as a shortest path through a network embedded in a state space. It generates optimal schedules under two assumptions. First, we assume that in each time period within the planning horizon, the machine must either be shut down or be producing some one item for the entire time period. Second, we assume that inventory holding costs are representable as a nondecreasing function of aggregate inventory. We provide a number of numerical examples that we solved using the algorithm. (Edited author abstract) 7 refs.

**093046 ECONOMIC LOT-SCHEDULING PROBLEM: A SIMPLE APPROACH.** A simple approach that selects good feasible solutions to the economic lot-scheduling problem (ELSP) has been presented. It is based on identifying the smallest subgroup of items to be manufactured in every production cycle. The procedure iterates starting with the first item and enlarging the subgroup of items until the fundamental period so obtained is feasible. The solution obtained satisfies some reasonable properties: the smaller the economic time of an item, the more often it is manufactured; the fundamental period is (almost) equivalent to the economic time of the subgroup of items manufactured every cycle. The subgroup of items manufactured every cycle is the smallest subgroup feasible, once previous properties have been satisfied. 7 refs.

**093048 EXTENSION OF PALMER'S HEURISTIC FOR THE FLOW SHOP SCHEDULING PROBLEM.** We describe a simple modification of Palmer's heuristic for scheduling jobs in a flow shop. The additional computation required is relatively small. The performance of the algorithm compares very well with that of the more sophisticated and better algorithm of Campbell, et al. (1970) at a fraction of the effort required by the latter. (Edited author abstract) 10 refs.

**093049 NETWORK SCHEDULING LIMITED BY SPECIAL CONSTRAINT AS A FUNCTION OF TIME COST.** The paper deals with the application of mathematical programming techniques to network analysis and network management in general. The authors show the application of linear programming to network scheduling when the problem is to minimize the total crashing cost and the required completion time is given. Finally the application of goal programming is presented in network scheduling in the case, when all kinds of constraints (time, resource, etc.) are introduced into the problem and the manager has to deal with multiple objectives which may

be in conflict. All kinds of network scheduling problems mentioned are illustrated through a detailed numerical example. (Edited author abstract) 3 refs.

**093050 IMPROVED BRANCHING SCHEME FOR THE BRANCH AND BOUND PROCEDURE OF SCHEDULING  $n$  JOBS ON  $m$  PARALLEL MACHINES TO MINIMIZE TOTAL WEIGHTED FLOWTIME.** All jobs and machines are assumed to be available at time zero. Machines work on jobs one at a time a pre-emption is not allowed. Setup times are included in the processing times which are sequence-independent, deterministic and known in advance. Some new and simple results are presented which are easy to implement to obtain an efficient branch-and-bound algorithm. A new and improved lower bound is developed which is easy to compute. (Edited author abstract) 14 refs.

**093051 DISPATCHING IN A MULTISTAGE JOB SHOP WHERE MACHINE CAPACITIES ARE UNBALANCED.** A realistic assumption is one in which machine capacities are not balanced such that one machine can be identified as a bottleneck. In this paper, the performance of selected dispatching rules in an unbalanced multistage job shop is evaluated to determine whether the performance is consistent for jobs which are routed through the bottleneck and for jobs which by-pass the bottleneck. This research identifies which type of sequencing rule performs best in a multistage job shop where capacities are not balanced (i.e. such that one work center can be identified as a 'bottleneck'). **093053 APPROXIMATIONS FOR THE TIME SPENT IN A DYNAMIC JOB SHOP WITH APPLICATIONS TO DUE-DATE ASSIGNMENT.** Using an exponential limit theorem and a heuristic decomposition of open queueing networks, we show that for a large class of dynamic job shops, the total time spent in a dynamic job shop can be approximated by an exponential random variable with an appropriate mean. Approximations for job shops that do not belong to this class are also developed. Numerical results show that the proposed approximations are in general very good. Application of these approximations in the assignment of due-dates is also illustrated. (Edited author abstract). 20 Refs.

**093054 DISCRETE TIME AVERAGE COST FLEXIBLE MANUFACTURING AND OPERATOR SCHEDULING MODEL SOLVED BY DECONVEXIFICATION OVER TIME.** The principal concern is to schedule operators over time to various activities of a manufacturing system for the purpose of optimizing some steady-state criteria. In mathematical terms, the problem is modeled as a deterministic, infinite horizon, discrete dynamic program. Our solution procedure is to convexify the problem to obtain a linear program, and then to

deconvexify the solution of the linear program over time to arrive at an optimal solution. Apparent loss in objective value due to the deconvexifications is circumvented with buffer inventories. The procedure is reduced to solving a sequence of linear programs and the complexity is stated in these terms. (Edited author abstract). 10 Refs.

**093055 DYNAMIC SCHEDULING AND ROUTING FOR FLEXIBLE MANUFACTURING SYSTEMS THAT HAVE UNRELIABLE MACHINES.** This paper presents a method for real-time scheduling and routing of material in a Flexible Manufacturing System (FMS). It extends the earlier scheduling work of Kimemia and Gershwin in which the FMS model includes machines that fail at random times and stay down for random lengths of time. The new element is the capability of different machines to perform some of the same operations. The times that different machines require to perform the same operation may differ. This paper includes a model, its analysis, a real-time algorithm, and examples. (Author abstract). 24 Refs.

Maimon, Oded Z. (Tel Aviv Univ, Tel Aviv, Isr); Gershwin, Stanley B. *Oper Res* v 36 n 2 Mar-Apr 1988 p 279-292.

**093056 WEIGHTED TOTAL TARDINESS PROBLEM WITH FIXED SHIPPING TIMES AND OVER-TIME UTILIZATION.** Shipping times are assumed to occur at fixed and specified points in time, and their number is much smaller than the number of jobs. The goal is to find an overtime utilization level and job sequence that yields a 'good' tradeoff between overtime cost and tardiness penalties. We begin by showing that the problem in its simplest form is NP-hard. We then present an approximate algorithm based on a capacitated transshipment formulation. This approximation provides a feasible solution along with its error bound. The algorithm is refined by incorporating the dominance relations of jobs. Extensive computational experience indicates that the algorithm is implementable in terms of both speed and accuracy. (Edited author abstract). 25 Refs.

**093057 MULTIPROCESSOR SCHEDULING WITH INTERPROCESSOR COMMUNICATION DELAYS.** We consider the problem of scheduling a set of  $n$  partially ordered tasks on  $m$  identical processors in order to minimize the makespan, where there is a communication delay between any pair of distinct processors. This problem is NP-hard. We provide a heuristic algorithm, called Earliest Ready Task (ERT) algorithm, to solve the problem. Among all tasks whose parent tasks have been assigned, an ERT algorithm is one that always chooses one task that can be processed earliest. We show that the makespan  $M$  generated by ERT algorithm always satisfies a given equation where  $M'$  the optimal makespan without considering communication delay and  $C_{comm}$  is the maximum communication delay in one chain. We also provide an algorithm to find this chain. The time complexity of implementing the ERT algorithm is  $O(mn^2)$ . (Edited author abstract). 12 Refs.

**093058 OPTIMIZATION BASED HEURISTIC FOR SCHEDULING PARALLEL PROJECT NETWORKS WITH CONSTRAINED RENEWABLE RESOURCES.** We present a model for the simultaneous planning of many individual project networks. We formulate the problem as an integer program that is similar to models found in the inventory/production scheduling literature. A Dantzig-Wolfe decomposition is used to obtain solutions to the linear programming relaxation of the problem. The algorithm selects a subset of these solutions to form a final schedule. Computational results

are presented. Extensions of the algorithm, including non-identical projects, alternative objective functions and implementation on a rolling horizon are also discussed. (Edited author abstract). 11 Refs.

**093060 MEAN VALUE ANALYSIS OF THE TRAVELLING REPAIRMAN PROBLEM.** We consider the machine repairman problem where the machines are spatially distributed and repaired by a travelling serviceman. We assume identical machines with exponential up times and general repair times. We also assume that the travel times between pairs of locations have identical, but arbitrary distributions. Assuming a work-conserving, non-preemptive service discipline, a semi-Markov model is developed and various performance measures are evaluated. Some applications of the model are discussed. The model developed here, is used elsewhere to develop approximations for a more realistic situation where machines are non-identical and travel time distributions between pairs of locations are also non-identical. (Author abstract). 22 Refs.

**093061 OPTIMAL PLANNING AND SCHEDULING OF ASSEMBLY LINES.** This paper explores the economic conditions under which single-model assembly lines are operated in a batch mode (through intermittent manufacture at higher production rates) rather than by the traditional method of continuous production at the demand rate. A model for optimizing the 'cycle time, station number' combination is developed through consideration of five factors: the learning, inventory, setup, balancing and facility costs. Economic justification for operating in a batch mode was found for total demands ranging from 20 to 4000 assembled products which is expected to include a sizable percentage of the total products manufactured in industrialized countries each year. Greatest savings occur for total demands in the order of 1000 products. (Author abstract). 26 Refs.

**093064 EVALUATING PROJECT SCHEDULING AND DUE DATE ASSIGNMENT PROCEDURES: AN EXPERIMENTAL ANALYSIS.** This study presents a number of important results for managers interested in scheduling projects and setting due dates. Using more information concerning the current work in progress, available resources, and activity precedent relationships provides a better due date estimate for a new project. A finite scheduling procedure (called SFT) consistently gives better due date estimates than simpler aggregate procedures. When some project due dates are set externally, due date performance deteriorates. The effort, measured by CPU time, for SFT to estimate a good due date depends upon the ratio of activity resources required to total resources available, rather than the number of activities across all projects. Similarities and differences between the results observed in this study and past due date job shop scheduling research are reviewed. (Edited author abstract). 30 Refs.

**093065 OPTIMALLY BALANCING LARGE ASSEMBLY LINES WITH FABLE.** A new algorithm named 'FABLE', obtains proven optimal solutions for ten 1000 task lines, which each possess the computationally favorable conditions of an average of at least 6 tasks per work station and a small number of between-task precedence requirements, in less than 20 seconds of IBM 3033U CPU time for each problem. A total of 549 problems of various characteristics are solved to determine conditions under which FABLE performs most and least favorably. Performance is sensitive to average number of tasks per work station, number of between-task precedence requirements (measured by 'order strength'), and the total number of tasks per problem. A heuristic variant of FABLE is also described. (Edited author abstract). 10 Refs.

**093066 SHIFTING BOTTLENECK PROCEDURE FOR JOB SHOP SCHEDULING.** We describe an approximation method for solving the minimum makespan problem of job shop scheduling. It sequences the machines one by one, successively, taking each time the machine identified as a bottleneck among the machines not yet sequenced. Every time after a new machine is sequenced, all previously established sequences are locally reoptimized. Both the bottleneck identification and the local reoptimization procedures are based on repeatedly solving certain one-machine scheduling problems. Besides this straight version of the Shifting Bottleneck Procedure, we have also implemented a version that applies the procedure to the nodes of a partial search tree. **093068 ADAPTABLE SCHEDULING ALGORITHM FOR FLEXIBLE FLOW LINES.** Consider a manufacturing line that produces parts of several types. Each part must be processed by at most one machine in each of several banks of machines. This paper presents an algorithm that schedules the loading of parts into such a line. The objective is primarily to minimize the makespan and secondarily to minimize queuing. The problem is decomposed into three subproblems and each of these is solved using a fast heuristic. The most challenging subproblem is that of finding a good loading sequence, and this is addressed using workload concepts and an approximation to dynamic programming. We make several extensions to the algorithm in order to handle limited storage capacity, expediting, and reactions to system dynamics. The algorithm was tested by computing schedules for a real production line, and the results are discussed. (Author abstract). 7 Refs.

## Monitoring

**093069 SCHEDULE MONITORING OF ENGINEERING PROJECTS.** A tool for monitoring, reporting, and controlling the progress of time-critical projects called progress plotting is presented. It helps distinguish between minor schedule slips and problems that call for serious management intervention. It also serves to evaluate planning accuracy on previous projects. Progress is shown by plotting the actual time used on a project against the completed percentage of the critical path. Control lines in the plotting space indicate probabilities of completing the project on schedule. If the progress line crosses a low-probability control line, managers may want to intervene and bring the project back on schedule. Crossing a high-probability control line means an early finish may be anticipated with confidence. The progress plot is comparable to the process-control chart used in manufacturing settings. 10 refs.

**093071 SIMPLE ALGORITHM FOR FLOWSHOP SCHEDULING BASED ON TOTAL PROCESSING TIME CRITERION.** Several computer based algorithms are available for the solution of  $n \times M$  flowshop scheduling problems, normally based on a single optimization crite-

rior. The algorithms proposed by Campbell, et al and Gupta are claimed to be efficient and yield near optimal solutions based on the minimization of makespan (throughput time) as the objective functions. Majority of the available algorithms are sometimes incapable of dealing with complex situations and become computationally infeasible. Keeping this in view, a simple algorithms has been proposed, based on total processing time criterion and multiple objective functions, for  $n \times M$  flowshop scheduling. The results thus obtained have been compared with those of Gupta. (Edited author abstract) 11 refs.

**093072 JOB-SHOP DECISION SUPPORT WITH A MICROCOMPUTER SPREADSHEET.** A simple microcomputer-based decision aid supports the production manager in evaluating alternative schedules by quickly displaying finished times and lateness. This simple tool is intended to assist an experienced scheduler do the job more quickly. There is no attempt to optimize, but merely to demonstrate the impact of alternative schedules. The main attraction of such a system is its simplicity: it takes advantage of the scheduler's experience, can be built with only moderate effort, and can be operated by even a relatively naive computer user. It is also relevant to the organizational realities of the situation. 5 refs.

**093073 OPTIMAL COMMON DUE-DATE WITH LIMITED COMPLETION TIME DEVIATION.** Given a set of  $n$  jobs with deterministic processing times and the same ready times, the problem is to find the optimal common flow allowance  $k^*$  for the common due-date assignment method, and the optimal job sequence  $\sigma^*$  to minimize a penalty function of missing due-dates. It is assumed that penalty will not occur if the deviation of job completion from the due-date is sufficiently small. Three lemmas are presented and a numerical example is provided to illustrate the use of the results to determine the optimal solution to the due-date determination and sequencing problem. (Author abstract) 16 refs.

Cheng, T.C.E. (Univ of Manitoba, Winnipeg, Manit, Can). *Comput Oper Res* v 15 n 2 1988 p 91-96.

**093074 DETERMINATION OF AN OPTIMAL COMMON DUE DATE AND OPTIMAL SEQUENCE IN A SINGLE MACHINE JOB SHOP.** We consider  $n$  jobs on a machine sequencing problems in which all jobs have a common due date and a deviation in its completion time occurs when a job is completed before or after the common due date. Starting with an arbitrary sequence we relate the problem to generalized linear goal program from which some basic results are proved using elementary properties of linear equations and a linear programming problem. Using these results and the idea of sensitivity analysis in linear programming, an algorithm is developed that determines the optimal due date and the corresponding optimal sequence yielding the global minimum value of the mean absolute deviation of the completion times of the jobs in the optimal sequence from the corresponding optimal common due date. In the end a numerical example to explain the algorithm is provided. (Edited author abstract) 17 refs.

## Testing

**093075 FEASIBILITY TEST FOR MULTI-PRODUCT LOT SIZE SCHEDULING ON ONE FACILITY.** Venuganti's necessary and sufficient condition for the feasibility of scheduling two products is extended to that of scheduling multi-products. Using this extended condition, this paper presents a succinct approach to test feasibility of a given set of schedule parameters (basic

period and multipliers) in an economic lot scheduling problem (ELSP). This is achieved by partitioning the integer linear programming (ILP) model originally given by Haessler and Hogue into smaller independent models by an efficient approach based on the Chinese Remainder Theorem. The present approach reduces the number of necessary variables and constraints of the ILP model drastically. For a small problem involving ten products or so, the test can be carried out very simply by hand. An example is given to illustrate the approach. (Author abstract) 17 refs.

## SCHOOL BUILDINGS See Also ASBESTOS—Health Hazards.

### Climate Control

**093076 SYSTEM UPGRADE.** Cave Spring High School was designed and built in the late 1960s. The original design consisted of a central heat pump plant using a cooling tower to either reject heat in the cooling season or to absorb heat during the heating season. A few years after construction of the original building, a new wing (18,000 sq ft) was added and is conditioned by all electric rooftop multi-zone units. In addition to the unit based control changes, a microprocessor-based facility management system now controls all major energy consuming HVAC equipment. Electronic zone temperature sensors, located strategically throughout the facility, feed environmental data back to the central control which performs logic functions to achieve efficient and economical control and maintain comfortable space conditions.

Crutchfield, Walter I. III (Cii Engineered Systems Inc, Richmond, VA, USA); Wash, Ronald L. *ASHRAE J v 30 n 6 Jun 1988 p 40-42.*

**093077 HVAC SYSTEMS REPLACEMENT.** Lumen Christi High School, located in Jackson, Michigan, was constructed in 1967. The gross building area is 155,000 sq ft. The classroom, cafeteria, administration portion of the building was heated and air conditioned using rooftop multizone, gas-fired air handling units. Based on the HVAC systems analysis, a closed loop water source heat pump system was recommended to replace the current rooftop multizone units. A microprocessor-based energy management system was installed to control the individual heat pumps and ancillary equipment. The system is also utilized to limit the building electrical demand peak by shedding various mechanical loads in a prioritized sequence to maintain a comfortable facility.

### Construction

**093078 LOW COST SCHOOL BUILT WITH INDIGENOUS MATERIAL AND TECHNIQUES AT HUB, BALUCHISTAN, PAKISTAN.** An experimental and demonstration low cost school has been built at Village Baroot, Hub, Baluchistan. The foundation and base course of the floor are made of soil cement stabilized material. The load bearing walls of the school have also been made of soil cement stabilized blocks. The roof has been precast and consists of battens, tiles and screed. In these portland cement has been replaced by finely grained granular slag up to 30 percent. A cement concrete floor has been provided in the school. Precast concrete arches have been fixed in the veranda for architectural purposes. The school is structurally sound and functionally very efficient. (Author abstract). 5 Refs.

### Energy Conservation

**093079 SOLAR-ASSISTED HEAT PUMP SYSTEM AND IN-GROUND ENERGY STORAGE IN A SCHOOL BUILDING.** An experimental solar-assisted heat pump system with a hybrid ground-coupled storage at the F.U.L. in Arlon, Belgium, is described. It includes a 382 m<sup>2</sup> solar roof, two types of water storages, heat storage in earth by horizontal exchangers, and heat pumps. One operating period (1984-1985) is analyzed. The data processed has shown that each of the subsystems has apparently performed adequately: annual collector efficiency is 0.41, heat pump C.O.P. range around 4. Despite important energy losses from the underground storage, the storage efficiency reaches 0.7. This effectiveness is mainly due to heat recovery below natural soil temperature and also to the use of buried tanks of short-term storage. The main difficulties are controlling the flow between these subsystems and developing an operating strategy that matches both the building's heat requirements and a good solar fraction. (Author abstract) 8 refs.

### Foundations

**093080 CONSTRUCTION OF GROUT COLUMNS IN CAVITIES IN THE EDWARDS LIMESTONE.** In 1985, Trinity Engineering Testing Corporation contracted with the Round Rock Independent School District to investigate the subsurface conditions at a new high school site located on McNeil Road southwest of Round Rock, Texas. The building was planned as a single and two-story structure. The school site is located on the geologic formation known as Edwards Limestone prone to solution cavities. At this site, the extent of the cavities precluded the use of deep drilled piers due to the excessive cost for drilling, casing and concrete. The evidence of recent collapse at the surface, and the very near surface cavities encountered in the core borings, made the use of shallow footings without grouting a high-risk solution. This left grouting as the only apparent workable solution.

Gunter, John A. (Trinity Engineering Testing Corp, Austin, TX, USA). *Tex Civ Eng v 58 n 2 Feb 1988 p 18-21.*

### Health Hazards

**093081 ASBESTOS IN SCHOOLS.** The containment or removal of asbestos from 733,000 buildings in the U.S. will cost an estimated \$100 billion over the 15-20 years. Recently, a boiler furnace explosion in a school located in an eastern state set in motion a series of events that is unusual for this type of occurrence. The explosion caused the insulation on the boiler, boiler breeching and connected piping to disintegrate and come to rest on the boiler room floor and other horizontal surfaces. The cleanup and removal was completed the next day and the air sampling results were within the Environmental Protection Agency's (EPA's) recommended standards. (Edited author abstract)

Scott, Timothy A. *Natl Eng v 92 n 3 Mar 1988 p 14-16.*

### Planning

**093082 SCHOOL COMPLEX IN THE GALLARATESE DISTRICT OF MILAN.** The various scholastic activities carried out in the teaching facility are all held in buildings which also leave ample space for the sports facilities and garden premises. All the blocks have a reinforced concrete loadbearing structure: beams and columns supported by strip foundations or r.c. footings. The floor decks are formed by a brick and r.c. composite structure, with the exception of the tower block, where precast T beams were used. The roof of the gymnasiums, swimming pools and workshops are ribbed prestressed concrete, whereas the precast panels are characterized by the exposed, pigmented surfaces which were bushhammered for finish. (Edited author abstract) In Italian and English.

Cavallotti, Carlo. *Ind Ital Cem v 57 n 11 Nov 1987 p 688-699.*

**093083 SAXA RUBRA HIGH SCHOOL ON THE VIA FLAMINIA IN ROME.** The architectural concept of the design resulted from the relation between volume and the particular site, the intended unity of the structure and its large structural grid. The compact monolithic two-floor structure rises from pilot is under which all the common facilities of the school are located. The reinforced concrete structure consists of in-situ cast columns and precast concrete beams and floors. Industrially produced 28 cm thick prestressed floor slabs were employed, enabling all spans up to 12 m in length to be covered. Precast cladding component panels, commonly marketed, were adapted to the required lengths and to the circular openings. (Author abstract) In Italian and English.

### Solar, Passive

**093084 PASSIVE SOLAR HEATED SCHOOL IN WALLASEY. VIII A STUDY OF THE LIGHTING.** The Wallasey School is recognized as an important building in the development of passive solar gain technology. This work reports an analysis of the lighting of the solar block of the school. A comprehensive photometric survey describes the visual environment of the school in both quantitative and qualitative terms. The results are compared with both statutory legislation and predictions using tools available to the original designers. Some general conclusions are drawn which emphasize the importance of visual aspects within the total design of passive solar technology buildings. (Author abstract) 18 refs.

### Space Heating

**093085 ENERGY STORAGE IN A CENTRAL HEATING SYSTEM: SPA SCHOOL FIELD TRIAL.** Cranfield Institute of Technology and British Gas plc have undertaken a collaborative programme of tests of a system which interposes a heat store between a boiler and a distributive central heating network. This has culminated in a field trial at Spa School in London. A thermally insulated 3235 l hot water store was installed in the circuit between the existing modular boiler set and the hydronic 'radiator' network. The pipework was arranged so that the heating system could be operated either as configured originally or in the storage mode, in which case two of the five modular boilers were valved off. The two configurations were operated alternately (for four week periods), and their performances were carefully monitored over the 1985/86 heating season. The storage system performed successfully with a 40% lower installed boiler capacity. Boiler cycling was reduced by a factor of 15 and the mean boiler load factor rose from 37 to 70%. Analysis of the results are given. (Edited author abstract) 10 refs.

### Ventilation

**093086 NATUERLICH UND MECHANISCH BELUEFTETE KLASSENRAEUME - VERGLEICH VON LUFTQUALITAET UND ENERGIEVERBRAUCH.** [Natural and Mechanical Ventilation of Classrooms, Compared in Terms of Air Quality and Energy Consumption]. Rooms with a high occupation density, e.g. classrooms, have high air change requirements which in view of the occurring draught cannot always be covered by opening windows. Especially in the winter season, windows can only be opened for short periods of time. The problem may be solved by installing decentralized ventilation systems. Combined with heat recovery units, these systems ensure lower heat consump-

tion than in naturally ventilated rooms. In German.

Rigos, Elstratios; Amonn, Wido. *Ki Klima Kaelte Heiz* v 16 n 5 May 1988 p 232-235.

**093087 BE UND ENTLUEFTUNG MIT WAER-MERUECKGEWINNUNG VON KLASSENRAEUMEN-EIN VERGLEICH VON LUTQUALITAET UND ENERGIVERBRAUCH.** [Forced Ventilation with Heat Recovery in Classrooms: A Comparison of Air Quality and Energy Utilization]. Rooms in which many persons are compelled to stay together at the same time, as e.g. classrooms, have a high demand for outside air. It can not always be guaranteed by opening the windows owing to the draft phenomena that take place. Especially, in low outdoor air temperature conditions, the windows can be opened only for short periods of time. As this is insufficient to improve air quality in the long run, a solution is proposed involving the use of decentralized ventilation devices equipped with heat recovery installations for each classroom. This can even lead to a lower demand for ventilation heat compared with naturally ventilated classrooms. (Translated author abstract). In German.

**SCINTILLATION** See Also ARGON—Scintillation; GASES, INERT—Radiation Effects.

**093088 MEASUREMENT OF SUBNANOSECOND SCINTILLATION DECAY TIMES BY TIME-CORRELATED SINGLE PHOTON COUNTING.** A time-correlated single photon counting system for measuring scintillation decay times is described in which the system time response function has a FWHM less than 220 ps. This is a two-scintillator system in which a time-to-amplitude converter (TAC) is started by gamma-induced flashes from a bright 500-ps FWHM scintillator closely coupled to a 14-stage photomultiplier. The TAC is stopped by single-photon pulses from an amplified high-gain microchannel-plate photomultiplier viewing the sample. A  $^{60}\text{Co}$  source is sandwiched between the start scintillator and the sample to be measured. The time correlation depends on the coincident excitation of both scintillators by the two  $\gamma$  rays from each nuclear disintegration. (Author abstract) 5 refs.

**093089 SCINTILLATION PROCESS IN THREE-COMPONENT SYSTEMS: THE LUMINESCENCE MINIMUM REVISITED.** The scintillation yield from the three-component system  $C+B+T$ , where  $T$  is the scintillation solute, is studied as a function of the electron fraction of component  $B$  for both  $\beta^-$ -particle excitation and for optical excitation of  $C$  both below and above its ionization threshold. When  $C$ =cyclohexane and  $T$ = $N,N,N'$ -tetramethylphenylenediamine, deep minima (20-40%) are observed when  $B$ =benzene under all excitation conditions, and much shallower minima (approximately 5%) are observed when  $B$ =toluene and then only for  $\beta^-$ -particle excitation and excitation above the ionization threshold of  $C$ . Analysis of these results indicates that the production of  $S_1$  state of  $B$  (i.e.  $B^*$ ) via either energy transfer from electronically excited  $C$  or via charge transfer from  $C^+$  followed by  $B^+e^-$ — $B$  is intrinsically inefficient in dilute cyclohexane solution. The analysis of the results illustrates the inadequacy of previous theories of the luminescence minima. 31 Refs.

**093090 PERFORMANCE COMPARISON OF SELECT ALKYL BENZENE AND DETERGENT BASED LIQUID SCINTILLATION COCKTAILS.** Tritium was employed in the evaluation of performance characteristics for six commercially available cocktails represented by the manufacturers to possess favorable disposal characteristics. Unidentified alkylbenzene organic solvents and/or triton-like detergents form the basis for these cocktails, which were evaluated in large (20 mL) and mini (7 mL) glass and polyethylene vials. The cocktails showed higher backgrounds, lower unquenched efficiencies, and greater quench resistance to nitromethane than a reference toluene based preparation. Detergent based cocktails were difficult to dispense accurately, and resisted sample incorporation. One cocktail lacked stability in polyethylene vials. (Author abstract) 9 refs.

**093101 STROBED MULTICHANNEL PHOTON COUNTER.** A strobed multichannel photon counter that operates in the visible region is built on the basis of a luminance amplifier with a microchannel plate and an Li-706 supervidicon. A pulse overvoltage supply mode for the microchannel plate provides the gain required for a counter plateau and permits strobing of the photodetector in the nanosecond (140 nsec) range. The counter noise is practically completely determined by the photocathode noise of the luminance amplifier. The multichannel counter has long-term stability, a simple electronic system, and a photodetector of small size. (Author abstract) 8 refs.

**093107 INFLUENCE OF PHOTON PEAK ARRIVAL IN THE TIMING OF PLASTIC SCINTILLATORS BY MEANS OF PULSED LASER AND OPTICAL FIBERS.** The influence of photon peak arrival in the laser-optical fibers timing system of a large array of plastic scintillators has been studied for different types of photomultipliers. The obtained results, helpful in properly designing the system are presented and discussed. The behavior of four types of photomultipliers to a short laser light pulse, injected in the scintillator they were coupled to, has been investigated. For EMI9964B, Philips XP2020 and Hamamatsu R2083 we have found that when the number of photoelectrons leaving the photocathode is larger than 15-20 and up to 60, the time resolution does not improve significantly and its behavior versus  $N_e$  is similar in all the PMTs. (Edited author abstract). 10 Refs.

**093108 DEVELOPMENT OF A NaI(Tl) DETECTOR WITH SUPERIOR PHOTON ENERGY RESOLUTION FOR USE ABOVE 100 MeV.** We have designed and tested a new high resolution NaI(Tl) total absorption scintillation counter. The detector has a measured resolution of 1.3% and 1.7% FWHM for 130 MeV photons and 330 MeV electrons, respectively. Computer simulations to account for loss of resolution due to pileup and energy spread of the beam indicate that the ultimate experimental resolutions at these energies are  $1.2 \pm 0.1\%$  and  $1.3 \pm 0.1\%$ . The resolutions at these two energies are at least a factor of 2 better than that of any other total absorption scintillation counter available today. Based on shower simulations, the detector is expected to have a resolution of approximately 130-200 MeV photons. (Edited author abstract). 9 Refs.

**093109 RESPONSE OF SCINTILLATORS TO HEAVY IONS - I: PLASTICS.** The response of various scintillator detectors to ions of  $A = 1-84$  and energies  $E/A = 5-30$  MeV has been measured and found to be linear above an energy of 100 MeV. Results are presented for a typical organic plastic scintillator including parameterizations of the data as a function of  $Z$ ,  $A$ , and energy. These results are applicable to the use of scintillators as heavy-ion detectors, with one calibration point giving a

normalization that allows use of the whole set of curves. The response functions are compared to previous parameterizations at lower energies and discussed in terms of the theory of  $\delta$ -ray formation in the scintillator. 18 refs.

McMahan, M.A. (Lawrence Berkeley Lab, Berkeley, CA, USA). *IEEE Trans Nucl Sci* v 35 n 1 Feb 1988, 34th Nucl Sci Symp, San Francisco, CA, USA, Oct 21-23 1987 p 42-46.

**093110 CONDENSED XENON SCINTILLATORS.** Liquid and solid xenon were investigated as scintillator media for the detection of charged particles. The LET dependence of the integral light output was studied over a wide range of ionization densities using alpha and beta particles and heavy ions of 1.4 MeV/amu. For solid xenon, scintillation decay times were measured by the delayed single-photon method. For liquid xenon, a compact transportable detector unit coupled to a liquid-nitrogen cryostat was designed as a detector for medium-energy heavy ions. With an integrated solid-state detector this unit can be applied as detector telescope for particle identification. 12 refs.

**093111 HIGH-EFFICIENCY SCINTILLATION DETECTOR FOR THERMAL AND HIGH-ENERGY NEUTRONS AND GAMMA RADIATION.** Subcriticality experiments require high-efficiency radiation detectors that are sensitive to neutrons (thermal and fast) over a wide energy range and to gamma radiation. A scintillation detector design that meets these criteria is described. It consists of two scintillators assembled on a single photomultiplier tube. One scintillator is a glass, loaded with lithium enriched in  $^6\text{Li}$ , and has high efficiency for low-energy neutrons. The second scintillator is a plastic having very good efficiency for higher-energy neutrons. Efficiency values are reported for various neutron energy ranges and for gamma radiation.

Chiles, M. (Oak Ridge Natl Lab, TN, USA); Mihalczko, J.; Blakeman, E.D. *IEEE Trans Nucl Sci* v 35 n 1 Feb 1988, 34th Nucl Sci Symp, San Francisco, CA, USA, Oct 21-23 1987 p 110-113.

**093112 NEUTRON DETECTION EFFICIENCY OF A LARGE SCINTILLATION CALORIMETER.** The efficiency of a mineral-oil-based scintillation detector, with 0.1% by weight of Gd within the walls of a modular substructure, was measured and calculated. From these measurements a detection efficiency of 28.6% can be deduced, for neutrons produced by a neutrino-proton reaction in the 56-t neutrino detector KARMEN, that neutrons from the inverse  $\beta$ -decay reaction in KARMEN can be detected with high probability via the  $\text{Gd}(n, \gamma)$ -reaction. A neutron efficiency of about 30% is thus possible, which means that high-efficiency neutrino detection is possible in KARMEN. 9 refs.

## Accessories

**093115 TIME-REFERENCING DEVICE FOR LARGE SCINTILLATION COUNTERS.** A device is described for time referencing of the output signal to the moment of entry of a charged particle into a large (> 100 mm) scintillation counter viewed on both sides by photomultipliers. The device, which employs 11 integrated circuits of series K500, contains two shapers, which are locked onto the constant part of the pulse leading edge, a coincidence circuit, and a circuit for locking onto the center of the time interval between photomultiplier signals. The device is compact and simple to adjust. The time resolution of a time-of-flight measurement system equipped with these devices is 300 nsec. The dead time of the device is 50 nsec. (Author abstract) 18 refs.

## High Temperature Effects

**093123 PERFORMANCE RESULTS FOR SCINTILLATION DETECTORS FOR HIGH TEMPERATURE ENVIRONMENTS INCLUDING MWD.** Sheet reflectors and elastomeric potting materials have become available for packaging NaI(Tl) scintillation detectors. The problem of compatibility of these materials with NaI(Tl) in the high-temperatures encountered in oil well applications is discussed. Specially treated systems that are compatible with NaI(Tl) to at least 200°C are described. Their performance is as good as that of traditional packed-powder systems, with only a 5 to 10% pulse height drop during initial exposure to 180°C. Additional data to 200°C show similar stable results, indicating potential application in the harsh MWD (measurement-while-drilling) environment.

Materials See Also PLASTICS—Scintillation.

**093124 CHARACTERISTICS OF THE SCINTILLATION RESPONSES OF SMALL LITHIUM GLASS DETECTORS TO ELECTRON EXCITATION.** The response characteristics of lithium glass scintillators to electron excitation have been determined for a range of electron energies, lithium concentrations and lithium enrichments. The characteristics determined were the absolute scintillation efficiency and intrinsic resolution. These measurements form part of a study of the possible use of such glasses for the determination of the tritium breeding in fusion reactor blanket experiments. The measurements were undertaken to investigate the effects of the gamma background on the signals arising from the tritium production reactions induced with the glass scintillators. Criteria for the selection of glasses most suitable for tritium breeding are discussed in terms of their measured characteristics. (Author abstract) 16 refs.

Dalton, A.W. (Australian Atomic Energy Commission, Menai, Aust). *Nucl Instrum Methods Phys Res Sect A* v A259 n 3 Sep 15 1987 p 545-549.

**093125 NEW POLYVINYLTOLUENE-BASED, RADIATION-RESISTANT PLASTIC SCINTILLATOR.** With the proposed Superconducting Super Collider (SSC) in the active planning stage and other particle physics accelerator facilities being upgraded to higher center-of-mass energies, it has become evident that the radiation levels (particularly gamma and neutron) will seriously degrade the performance of current detector systems. Specifically, the SSC is expected to produce (in the forward region) an annual dose of ten megarad. At the University of Florida, an ongoing effort is being made to produce a radiation resistant plastic scintillation. The plastic scintillator, doped with p-terphenyl and 3-hydroxyflavone fluors in a polyvinyltoluene base, and heated in an argon atmosphere to accelerate recovery, has significant radiation resistance. 3 Refs.

**093126 MEASUREMENT OF THE LIGHT YIELD OF COMMON INORGANIC SCINTILLATORS.** The light yield in photons per magaelectronvolt of some common inorganic scintillating crystals has been measured with silicon photodiodes. Incident particles are gammas in the 1-MeV region. The light signal was

calibrated against 60-keV gammas converted directly in the photodiode depletion layer. Among the tested materials CsI(Tl) gave the highest light yield of 52,000 photons/MeV deposited energy. 9 refs.

**093127 NEW SCINTILLATING GLASS FOR HIGH ENERGY PHYSICS APPLICATIONS.** A scintillating glass has been developed containing cerium (3+) oxide in an aluminate host glass. In this material the scintillation emission spectrum is red-shifted relative to that observed for  $Ce^{3+}$  in silicate glasses. Emission and absorption spectra are more widely separated in the aluminate composition, suggesting that such glasses might have improved light-transmission properties. The refractive index is high, making it a potentially interesting material for use in fiber-optic tracking detectors. 3 refs.

## Medical Applications

**093128 GATED THALLIUM SCINTIGRAPHY IN PATIENTS WITH CORONARY ARTERY DISEASE: AN IMPROVED PLANAR IMAGING TECHNIQUE.** The use of thallium scanning in the assessment of myocardial perfusion is well established. However, myocardial contraction leads to significant blurring of standard static images. By using electrocardiographic gating and a high sensitivity collimator, multiple view gated scans can be acquired prior to thallium redistribution. Reporting of these images on cine loop display in 100 consecutive patients undergoing coronary arteriography and 14 volunteers results in improved visual assessment of regional myocardial perfusion and, in information on left ventricular function. Predictive accuracy improves from 85% to 94% with gated imaging. Gated thallium scanning could be readily applied in most centers using thallium at no extra cost and with improved predictive accuracy in the non-invasive detection of significant coronary disease. (Edited author abstract) 20 refs.

## Performance

**093129 DETERMINATION OF THE LIGHT RESPONSE OF BC-404 PLASTIC SCINTILLATOR FOR PROTONS AND DEUTERONS WITH ENERGIES BETWEEN 1 AND 11 MeV.** The response of BC-404 plastic scintillator is measured up to 11 MeV for protons and up to 8 MeV for deuterons using a time-of-flight spectrometer. It is shown that the response is nonlinear in this energy range and can be described very well using a four-term polynomial in energy. Earlier response curves which were extrapolated from high energy data and from interpolation of low energy data at widely separated energies are nearly linear in the low energy region. A comparison has been made between our new measured data and the existing curves. (Author abstract) 12 refs.

**Standards** See RADIOACTIVITY MEASUREMENT—Standardization.

## Testing

**093131 RESOLUTION TESTS OF CsI(Tl) SCINTILLATORS READ OUT BY PIN DIODES.** Cylindrical CsI(Tl) scintillators of 38 mm diameter and 100 mm length read out with PIN diodes of 400 mm<sup>2</sup> area were tested with respect to their response to medium energy light particles (p, d, t,  $\alpha$ ). Resolutions of better than 1% were achieved for 50 MeV protons and 90 MeV  $\alpha$ -particles. For many crystals the resolution was found to be limited to 2-3% by local crystal nonuniformities which caused variations of the light output efficiency of several percent. A bench test is described which allows the detection of inhomogeneities to better than 0.5% accuracy. The quality of particle identification obtained with  $\Delta E-E$  and pulse shape discrimination techniques are investigated as a function of count rate. (Author abstract) 11 refs.

## SCRAP METAL

### Costs

**093132 HOW MUCH DOES SCRAP REALLY COST.** There are several methods used to determine the unit product cost of scrap in manufacturing, and some of these methods do not give correct answers. Scrap costs are usually higher than expected, and the methodology presented in this article gives a consistent and accurate method for determining correct scrap costs. Scrap calculations are often based upon a percent scrap rate, but they can also be evaluated on an actual unit basis. To compare the various methods, an illustrative example using the scrap percentage basis is presented. 2 Refs.

Creese, Robert C. *Cost Eng (Morgantown WVa)* v 30 n 7 Jul 1988 p 15-19.

### Processing

**093133 GRUNDLAGEN DER BERECHNUNG UND KONSTRUKTION VON SHREDDERN SOWIE BETRIEBSERGEBNISSE.** [Basic Principles of the Design and Construction of Shredders and Their Operational Results]. Based on the analysis of the technological state-of-the-art in shredder construction, this report deals first with the principles underlying scrap processing in shredders with horizontally pivoted rotor. It then discusses the determination and evaluation of variants for structural design of the individual machine components and their assembly. A method of computing the nominal driving power of shredders is presented. Results obtained with the operation of a shredder with a nominal driving power of 1600 kw are described. (Translated author abstract) In German. 73 refs.

**093135 EFFECT OF THE THICKNESS OF THE FERROMAGNETIC FLUID LAYER IN A MAGNETOHYDROSTATIC SEPARATOR ON THE EFFICIENCY OF THE CONCENTRATION OF CRUSHED COPPER-LEAD SCRAP.** The effect of the thickness of the ferromagnetic fluid layer in the working chamber of a magneto-hydrostatic separator on the concentration efficiency is shown. On the basis of experimental studies, analytic expressions for the variation of the layer thickness are obtained for ferromagnetic fluid layers with magnetization of 9, 13 and 25 kA/m. It is shown that at an optimal ferromagnetic fluid layer thickness mutual contamination of the separation products is minimal. The concentration efficiency in this case is 98.1%. 4 refs. In Russian.

Kravchenko, N.D.; Bondarev, N.A.; Chuprina, Yu.V. *Izv Vyssh Uchebn Zaved Tsvetn Metall* n 4 1987 p 2-4.

**093136 RECLAMATION OF TUNGSTEN CONTAINING SCRAP MATERIALS: ECONOMIC AND TECHNICAL ASPECTS.** The authors discuss some of the technical and economic aspects of recycling tungsten scraps, its availability, recycling methods, and some of the benefits that have been obtained in using the 'Zinc Process' over the past 12 years. In recent years the sorting of feed material for the 'Zinc Process' has become more complicated and technically challenging because of the increasing use of cermets, ceramics, coated inserts, and Ni- and NiCr-binder carbides. (Author abstract).

**093139 TEST SIEVING METHODS.** In spite of the considerable standardization work that has been done, there are hundreds of granular materials for which sieve analysis data are desired but for which standard test procedures have not been established or published. One of the objectives of this manual is to meet this need for supplementary procedures for specific materials by summarizing the most accepted general procedures for making sieve tests and also by providing guidelines for developing new standard sieve analysis procedures when none are available. The manual describes wire cloth sieves, perforated plate sieves, precision electroformed sieves, center-line sieves, samples and sampling, general test sieving procedure, hand sieving method, mechanical sieve shaker method, wet testing, combined wet and dry testing, weighing, calculation, graphic presentation of test results, care and cleaning of test sieves, and offers miscellaneous suggestions. Eight appendices list U.S. standard sieve series, and offer standards for sieve analysis procedures. A glossary is also presented. 20 refs.

Anon. *ASTM Spec Tech Publ* 447B 1985 46p.

**093140 COMPACT SIZING SCREEN DISPELS TEXAS-SIZE DOUBTS.** The article describes the operations of Royer/Mogensens's test center in Kingston, Pa. The center uses a full-size 1/2 meter Sizer measuring about 8 feet deep by 3 feet wide by 5 feet deep. The Sizer is able to produce very clean material.

## Calculations

**093141 APERTURE SIZE IN A SCREEN OF PLAIN DUTCH WEAVE.** In an investigation into the aperture of the effective size in a screen of plain Dutch weave, it was found that a spherical particle is obliged to pass through two areas: the space between two wefts on the surface of the screen and an inner triangular space surrounded by a warp and two wefts. The size of the triangular area was estimated geometrically and compared with the results of screening experiments using glass beads and silica sand. The experimental results were related to the original size distribution of the material, the number distribution of screened oversize and undersize, and the curve for the efficiency of separation of particles. (Edited author abstract). 7 Refs.

**Design** See COAL PREPARATION—Screening; CRUSHERS—Design; ORE TREATMENT—Screening.

## Materials

**093142 POLYURETHANE AND RUBBER SCREEN DECKS, I.** A concise description of rubber and polyurethane vibrating screen decks is provided followed by the problems relating to screen aperture size selection. The latest techniques of manufacture and assembly of ready-to-fit screening systems is described. The operational characteristics of these systems are described, and the results of several successful applications are discussed. Well-proved methods of screening difficult ores with near-mesh or wet characteristics are discussed. The success of these systems will ensure their steady growth in various applications. (Edited author abstract) In German and English. 5 refs.

Wolff, K. *Aufbereit Tech* v 28 n 6 Jun 1987 p 322-330.

## Performance

**093143 SIEBBODEN AUS POLYURETHAN UND GUMMI - TEIL 2.** [Polyurethane and Rubber Screen Decks, II]. Rubber and polyurethane screen panels have been developed against a background of decades of screening experience and have proved worldwide for over fifteen years to be excellent in use. They are the result of a well balanced combination of steel, synthetics or rubber and have found a secure place in all processing plants. Modular screen panels of the type resting and held down only on two opposite sides lead to a simple and cost effective support structure offering additional advantages. The ease of handling of the relatively small modules with low weight as well as optimal stackability, low maintenance and ease of exchange, reduce the running costs of plants. Continuing growth in the use of modular screen panels can be expected refs 8. In German and English.

Wolff, K. *Aufbereit Tech* v 28 n 7 Jul 1987 p 383-391.

**093144 SCHARFE KLASSIERUNG VON KUNSTSTOFFEN MIT NASSSIEBEN** [Sharp Classification of Plastics on Wet Screens]. On a continuously operating wet screen about 10 per cent undersize of plastics pearl material have to be screened out at 400. Rotating water nozzles are used to clean the screen apertures. Three problems were investigated, theoretically and by making use of a test-model: jammed grains were pushed out of the screen meshes by cleaning water ejected from the nozzles; the transport of the coarse material was dealt with as a function of the nozzle parameters; and the quasi-completeness of separation of the feed sizes was found to be attainable, as a function of the geometry of the screen and its mode of operation. If accurately tuned the stream-type wet screen is able to satisfactorily master difficult tasks. (Edited author abstract) 1 ref. In German and English.

Baecker, J. *Aufbereit Tech* v 28 n 7 Jul 1987 p 392-396.

**093145 HOHERE DURCHSATZRATEN BEI DER NABSIEBKlassierung IM FEINBEREICH MIT 'BANANEN' - UND UNTERWASSERSIEBMASCHINEN.** [Higher Feed Rates for Wet Screening in Fines Ranges with 'Banana' and Underwater Screening Machines]. Wet screening is finding increasing application in fines ranges. The construction of larger screening units for higher feed rates and the continuous development of improved synthetic screen decks have made a significant contribution to this. Two special kinds of screening machines for wet screening, the banana screen, a high-speed screen with up to 30 m<sup>2</sup> screening area, and the underwater screening machine, with up to 10 m<sup>2</sup> screening area, can be applied to cut-points down to 0.3 mm. Depending on the sizing work, the specific feed rate is between 10 and 30 metric t/m<sup>2</sup> h, even, with high product-quality requirements, and this occurs with low water consumption. Due to the precise cut-point and long operating life of synthetic screen decks, the machines have been frequently used with success for extremely abrasive raw materials, such as glass sand, milled quartz, etc. (Edited author abstract). In German and English.

Singh, B.K. *Aufbereit Tech* v 28 n 7 Jul 1987 p 397-403.

**093146 EINSATZ VON GUMMISIEBELAEGEN IN DER KIESAUFBEREITUNG AUF SIEBMASCHINEN UND RUNDSORTIERERN.** [Use of Rubber Screen Mats on Screening Machines and Circular Sorting Units in Gravel Processing]. In the case of a gravel plant in Denmark it is shown that 112 out of a possible 142 screen mats are made of rubber. By means of special aperture shapes, certain types and thicknesses of rubber adapted to screening machine characteristics and screening problems, long-term, trouble-free, no-maintenance operation can be achieved. In spite of higher initial investment costs for rubber screen mats, their long operating life and the cost/utilization ratio favors the use of rubber screen mats. In German and English.

Bendzko, J. *Aufbereit Tech* v 28 n 7 Jul 1987 p 410-414.

## Plastics Applications

**093147 SCREENING OUT NOISE, DUST PROBLEMS.** A New England producer, seeking a solution to the noise/dust problem, started switching to urethane screening media about two years ago. The change has reduced plant noise - and complaints - and reduced blinding caused by water-mist dust control. Operating costs - based on longer wear life and fewer blinding problems - are also lower. The greatest benefit according to Balf Co., Newington, Conn. is that finer material will not build up on the urethane screens under moisture conditions necessary to effectively control dust.

Drake, Robert (Pit & Quarry, Cleveland, OH, USA). *Pit Quarry* v 80 n 11 May 1988 p 24-26.

**093148 URETHANE SCREENS PROVE DURABLE FOR DRAVO.** One of the challenges facing older aggregate processing plants is updating equipment to remain cost competitive. Positive changes in the wear characteristics of modern screening media can be accommodated by simple retrofits. Dravo Basic Material Co.'s Camp Dennison, Ohio facility - originally built in the 1940s - has cut screening costs by switching to urethane and rubber-coated products.

Kuhar, Mark S. (Pit & Quarry, Cleveland, OH, USA). *Pit Quarry* v 80 n 11 May 1988 p 38-39.

**Vibrating** See Also BLAST FURNACES—Charging Equipment; SCRAP METAL—Separation; VIBRATIONS—Measurements.

**093149 SELECTING THE RIGHT VIBRATING SCALPER: DETERMINATION OF SIZE, DECKING AND FRAME DESIGN.** Vibrating scalpers perform important functions in aggregate mining and mineral plants and can be the key to a smooth running and profitable operation. It is important to select the correct size unit and to specify the optimum decking and live-frame features to meet requirements. A scalper can be described as an extra heavy duty vibrating screen, typically designed with grizzly bars or heavy-duty plate separating at large openings and handling larger material (typically +10in). The function of scalping is the separation of oversize from predominantly finer feed.

Luadzers, Leon (Hewitt-Robins, Columbia, SC, USA). *Quarry Manage* v 14 n 10 Oct 1987 p 43-45.

**093150 SCREENING EFFICIENCY FOR PLANAR AND SPATIAL DRIVE MECHANISMS.** Screen oscillation with a crank pitman, spatial crank slider, bent shaft, and a quick return drive mechanism for separating over and under sized particulates was simulated. An index was used for evaluating the effect of the different drives. It was based on the velocity of the particulate relative to the screen and on the opportunity the particulate had to penetrate the screen. The index indicated that the crank pitman drive was better for the screening of particulates than the other three. (Author abstract) 3 refs.

Tan, Jingalu (Univ of Minnesota, St. Paul, MN, USA); Harrison, H. Page. *Trans ASAE* v 30 n 5 Sep-Oct 1987 p 1242-1245.

**093151 SKUTECZNA WYDAJNOSC PRZESIEWANIA WIBRACYJNEGO.** [Effective Output of Vibration Screening]. Based on a mathematical model of screening the real probability of single grain passing through a sieve cloth aperture as a function of changing process parameters was investigated. The results of experiments obtained proved the correctness of the previously developed model of sieve classification and were the base for the new developed equations for determination of an effective screening output, its efficiency and surface area of the screen needed. The formulas have a universal

application and may be employed for different materials and conditions of screening process. (Author abstract) 8 refs. In Polish.

**093152 NEUE PNEUMATISCHE MAGNETSIEB-MASCHINE DER FIRMA RHEWUM.** [New Pneumatic Magnetic-Screening Machines of the Rhewum Firm]. Studies were made of the screening of ultrafine bulk materials on Rhewum's high-performance screening machine, in which the screen cloth is subjected to direct excitation. Given the good results achieved in fine and medium screening (in the range 0.1 to 6 mm) with the tried and tested principle of direct excitation of the screen cloth, and given the latest knowledge of air-assisted extremely fine grading, pilot-scale separation trials were carried out at a particle size below the critical size for purely mechanical screening (0.1-0.2 mm). Using a combination of both direct vibration of the screen cloth by means of electro-magnetic vibrators and pneumatic screening, a high feed rate and the throughput performance is achieved for products having specific properties and particle size distribution such as to make successful continuous screening extremely difficult. (Edited author abstract). 3 Refs.

## Wear Resisting

**093153 WECHSELSIEBBOEDEN AUS POLYURETHAN UND GUMMI IN EINEM SYSTEM.** [Clamp-on Screen Decks of Polyurethane and Rubber Together in One System]. The Gummi Kueper company supplies a system for wear-resistant clamp-on screen decks known as V 100, its special feature being the variety of different materials used in one system with 100% compatibility. On the basis of operational experience, it is shown that virtually all bulk materials can be sized (graded) in a pegging or clamp-on system. (Edited author abstract) In German and English.

Dietz, G. *Aufbereit Tech* v 28 n 11 Nov 1987 p 665-669.

## SCREW THREADS See Also FASTENERS—Design.

### Analysis See BOLTS AND NUTS—Analysis.

### Cutting See SCREWS—Thread Cutting.

## Fatigue

**093154 FATIGUE STRENGTH OF MACHINED SCREW THREAD (EFFECTS OF LOADING MODES IN FATIGUE TEST).** The effects of various kinds of factors on the fatigue strength of machined screw thread connection generally used as the fastener of machine components are examined. Effects of materials (i.e. heat-treatment), fastening force, yielding pre-tension or pre-compression before the oscillating loading test and lubrication between the connecting surfaces are chosen as the factors. Fatigue tests are performed for both types of screw thread, and bolt-nut connections made of normalized or tempered S 45 C, and obtained results are investigated in detail. Consequently, the effects on the fatigue strength are clarified. Furthermore, the strain hardening caused at each step of the machining and loading process is discussed. (Author abstract) 6 refs. In Japanese.

## Finishing

**093155 DISC TOOL FOR BURNISHING WORM THREADS.** A disc tool was designed for burnishing the worm used in the power reduction box of the SMR-026/1 ore extraction machine. The proposed disc tool design and basic parameter calculation method can be used for

hardening other types of helical surfaces. The tool is simple both to use and to produce, and can be used widely in production.

Sogoyan, M.T. *Sov Eng Res* v 7 n 2 Feb 1987 p 47-48.

## Grinding

**093156 PRODUCTION ENGINEERING TECHNOLOGY.** It is essential to ensure during the screw grinding process not only a low degree of heat conduction into the workpiece (which is attained by reduction of finish grinding conditions) but also rapid heat elimination from the workpiece. In grinding of reversing screws oil coolants (oil grades I-12A and I-20A) are in predominant use and they facilitate production of the requisite surface layer qualities and of the screw profile accuracy. This article gives the results of comparative efficiency investigations of oil grade I-12A and of 6 percent 'Aquemus' emulsion, both of which are delivered into the cutting area by spraying during the rough thread grinding operations on a reversing leadscrew of a typical 50 × 10mm size, made from hardened steel grade 8KhF (HRC 59-63), using wheels grade 44A16M38K5. The essential advantage of coolant delivery by spraying lies in the simplicity of the method and in efficient washing of the workpiece, which results in its effective cooling. 4 Refs.

## Manufacture See GEARS—Worm.

## Measurements

**093157 AUTOMATIC MEASUREMENT OF SCREW PITCH ERROR BY THERMOPLASTIC HOLOGRAM.** A non-contact measuring method is proposed for the screw pitch error utilizing thermoplastic hologram instead of silver-halide plate hologram, and then the possibility to realize this method is experimentally investigated. The pitch signal is obtained by illuminating the hologram with both signal and reference beam, and the positional pulse is obtained through the electric circuits. (Edited author abstract) 5 refs.

**093158 DURABILITY OF TITANIUM ALLOY COMPONENTS WITH ROLLED THREADS UNDER CYCLIC LOADING.** Weakening of threaded joints, as a result of stress relaxation under the effect of cyclic loads, is one of the prevalent forms of operational failures in various machines and structures. The objective of the investigation was to carry out comparative tests for relaxation resistance and fatigue strength of free and working threads produced by two methods: cutting and rolling. Testpieces of two types made of titanium alloys type VT16 and VT9 were subjected to stress relaxation tests under cyclic loading. The results are evaluated for both methods. 6 refs.

## Tapping

**093159 NON-CUTTING TAP WITH AN ALTERNATING SCHEME OF THREAD FORMING.** Described is the design of a non-cutting tap forming the thread profile alternately by thread turns on the engaging and sizing portions. This threading process brings with it a substantial reduction of radial forces and contact stresses (as compared with the standard tapping method) and this provides thread production on the closed contour principle not only in non-ferrous materials but also in steel and in other materials, which are difficult to machine. Calculation recommendations are made for practicable sizes of taps; test results are also given. (Author abstract)

## Design

**093161 DESIGN RELIABILITY IN FASTENING.** Superior strength, safety and reliability have ensured the place of the socket screw as a fastener for high technology hydraulic requirements. A simple manufacturing 'tool' by many standards, the socket screw has a diversity of applications unmatched by any other form of fastening. It is now viewed in many hydraulic related industries as the production and design tool, combining the ability to fit exactly and be aesthetically acceptable while coping with the tensile loads required. The production of 'special' socket screws in small quantities, with diameters and often long lengths is applied to hydraulic production problems. (Edited author abstract)

White, A. (Non Standard Socket Screws Ltd). *Power Int* v 33 n 389 1987 p 165.

## Hardening

**093162 SELECTION OF ALLOYS FOR HARD-FACING SCREWS OF EXTRUDERS.** The authors examined three groups of hardfacing alloys with different alloying systems. The alloys examined were deposited on the specimens by the plasma method. The filler material for hardfacing was represented by industrial and experimental powders of the alloys produced by dispersing liquid metal with nitrogen. The first group included the chrome-nickel alloys Nos. 1-3 with boron and silicon. The second group consists of the alloys Nos. 4-7 based on cobalt and alloyed to various degrees with tungsten, chrome, and carbon. The third group includes the wear-resistant alloys Nos. 8-11 based on iron and differing in the alloying system and the type of structural hardening. The test results show that almost all the alloys tested, with the exception of alloys Nos. 1 and 11, form mainly cold cracks in the deposited layer. A large number of cracks distributed at the edges of the bead in the form of fine tears formed in deposition of the alloys Nos. 4, 5, and 7. 7 refs.

## Manufacture

**093163 CHANGES IN SCREW MANUFACTURING.** The demands made on screws have been increasing considerably in recent years. For instance, in mass production screws are no longer screwed in by hand but are fastened automatically by screw-in devices. One condition for trouble-free production of screws and screw fastening corresponding to tightening requirements must be first-class screw products of constant quality. The article discusses trends in the improvement of quality by manufacturing processes.

## Mechanical Properties

**093164 WITHDRAWAL STRENGTH OF SCREWS FROM A COMMERCIALLY AVAILABLE ME-**

**DIUM DENSITY FIBERBOARD.** Tests carried out to determine the holding strengths of various sizes of sheet metal type screws in the face of a commercially available medium density fiberboard (MDF) indicated that withdrawal strength could be predicted by means of an expression, given in the paper, that relates withdrawal strength (lb), internal bond strength (psi), diameter of the screw (in.), and depth of embedment of the screw (in.). Similarly, tests carried out to determine holding strength in the edge of the MDF included in the tests indicated that withdrawal strength could be predicted by another expression relating the same variables. Withdrawal strengths were about 13 percent higher when optimum pilot holes were used than when pilot holes were not used. (Edited author abstract) 7 refs.

**Stainless Steel**

**093165 GALVANO-MECHANICAL TIN PLATING OF 300 SERIES STAINLESS STEEL SELF-TAPPING SCREWS.** A galvano-mechanical tin plating process is described. After a pretreatment cycle in a tumbling mill and rinsing, the glass tumbling media is added to the mill along with an adequate amount of ambient fresh water to just cover mass of parts and media. The plating mill is rotated at approximately 150 surface feet per minute and, in sequence, mild acid compounds and surface preparation concentrates are added, along with a copper coating chemical and the proprietary stainless steel tin finishing compound. In approximately 20-25 minutes, a combination of chemical displacement or galvanic reactions and the mechanical burnishing of the glass media, produce a thin, bright, lubricious coating of tin metal of about 2-3 microns in thickness. 6 refs.

**Stresses**

**093166 STIFFNESS OF A PRE-LOADED BALL SCREW.** The stiffness of a pre-loaded ball screw is investigated as the stiffness of the spacing disc between the nut halves ranges from infinity to a small value. The stiffness equation is derived on the basis of Hertzian contact between the balls and the guiding grooves. The stiffness of the ball screw rises as the spacing disc stiffness is increased and the high stiffness is maintained until the pre-load is lost. The calculated stiffness approximately agrees with the experimental one with a small externally-applied load but the values deviate as the externally-applied load is increased. When the spacing disc stiffness becomes larger, the agreeable range between experimental and calculated values extends to that of a wider externally-applied load. (Author abstract) In Japanese. 7 refs.

**Thread Cutting**

**093167 OPTIMIZATION OF A PROGRAMMED MULTIPASS METHOD OF CUTTING SCREW THREADS ON LATHES.** The authors developed an alternative pass program that accounts for the thickness limitations on the layer being cut. The new program is based on the same generator pass program, equal areas of cut on each successive pass. It differs in that the trajectory of the cutting edge of the tool from pass to pass is not parallel to the generatrix of the thread's profile but is at a definite angle to it. In program, this angle is 3° on the first four passes and is increased by 3° after every fourth subsequent pass. A test of this pass program indicated

that the shavings were coiled and broken up in all the preliminary thread-cutting passes and were rinsed away easily by the cutting fluid without the operator's intervention. These pass programs have enabled us to create optimal conditions for the use of hard alloy cutting tool bits. This change has produced an increase in their durability by several factors (with wear-resistant coatings) under stable chip-breakup conditions.

**093168 GEWINDEREHEN MIT HARTMETALL-WENDESCHNEIDPLATTEN.** [Thread Cutting by Turning with Indexable Carbide Inserts]. According to DIN 8589, thread cutting is screw cutting for generating a thread by means of a single-profile turning tool. Thread cutting is substantially different from plain turning: The various parameters can be varied in plain turning regardless of each other to adapt to the cutting process going on. In thread cutting, however, geometry and profile are determined by the feed rate and cannot be adapted to the individual metal cutting process. The operation can be performed on both conventional and special thread cutting lathes and permits the production of accurate threads with good surface finish by means of simple low-cost tools. (Author abstract). 3 Refs. In German.

**093169 USE OF A CONICAL SCRUBBER TO REMOVE SULFUR DIOXIDE FROM SINTERING-MACHINE WASTE GASES.** An increase in the productivity of the sintering machines at the Magnitogorsk Metallurgical Combine has been accompanied by an increase in the volume of sulfur dioxide-bearing waste gases which are generated. The technology proposed by the institute VNIIchermetenergochistka for removing SO<sub>2</sub> from the gas with a conical scrubber ensures the cleaning of a large amount of gas due to a reduction in downtime and the amount of limestone suspension necessary. Use of the new scrubber also lowers electric power costs and the cost of gas cleaning.

**093171 EXPERIMENTAL RESULTS FROM A PLATE-COLUMN WET SCRUBBER WITH GAS-ATOMIZED SPRAY.** A pilot wet scrubber was examined experimentally. It is constructed like a plate column. Its plates are designed to set the gas into a whirling motion with tangential velocities of up to 25 m/s and to ensure a uniform distribution of the liquid throughout the gas flow. Particles suspended in the waste gas are collected by gas-atomized droplets to yield cut diameters between one and two microns. Energy consumption is lower than in the case of other scrubbers. The scrubbing mechanisms are analyzed by examining the measured pressure drops. Finally, methods of determining the collection efficiency are discussed and an empirical approach to its calculation is presented. (Author abstract) 10 refs.

**Analysis**

**093173 PECULIARITIES OF INSTALLATION OF VENTURI SCRUBBERS IN SUCCESSION.** It was found that the efficiency of dust collection in Venturi scrubbers (in the case of single-stage battery or group assembly of Venturi tubes) depends strictly on the energy consumption by them. A mathematical analysis showed that in the low-pressure mode of operation of the Venturi scrubbers, successive multistage installation of the latter is preferable to the single-stage one for equal hydraulic resistance. The authors assessed the efficiency of dust collection experimentally in one, two, and three successively placed diffuserless Venturi scrubbers. The investigations were conducted on real gases leaving the drying drum of the rock phosphate meal plant. The concentration of the dust of the rock phosphate meal in the gas before the Venturi scrubber varied within 0.4-4.5 g/m<sup>3</sup> (under normal conditions). The experiments performed reiterate the conclusion that the largest particles are collected selectively only in the first section (in the direction of the gas flow) of the apparatus where the median particle diameter diminishes on the average from 5.13 to 1.48 μm. 9 refs.

**093175 MULTITECHNIQUE CORROSION MONITORING IN FLUE GAS DESULFURIZATION SYSTEMS: PHASE 1.** The capabilities of a multitechnique electrochemical monitoring system for monitoring corrosion in the aggressive flue gas condensate that forms as thin films on the surface of scrubber outlet duct walls have been evaluated. The system employs a corrosion probe incorporating several discrete elements made of the Type 316L stainless steel used in the ductwork under study. The system monitored corrosion behavior using four techniques simultaneously, based on electrochemical impedance, electrochemical potential noise, galvanic coupling current using zero resistance ammetry, and electrochemical current noise. The corrosion monitor operated successfully at two test sites. The system distinguished between periods of pit initiation, pit propagation, passivity, and uniform corrosion and demonstrated direct relationships between these corrosion responses and changes in operating conditions.

**Costs**

**093176 CAPITAL AND OPERATING COSTS OF WET SCRUBBERS INSTALLED ON COAL-FIRED UTILITIES IMPACTING THE EAST COAST.** A computer program has been written to determine the cost of building and operating wet scrubbers on individual coal fired utilities in the states where emissions are likely to affect the acid rain problem in the eastern United States. The program differs from many other estimates since it

calculates the cost for each of 831 individual sites. The capital costs for installing scrubbers on the top fifty sulfur oxide emitting plants will be about \$20 billion. This will result in an increase in the cost of electricity on an average of 0.88 cents/kWh and a reduction of sulfur oxide emissions from 1980 of 7,100,000 tons per year. An additional reduction of at least 1,000,000 tons per year can be obtained by requiring all plants burning oil to burn low sulfur oil. The SO<sub>2</sub> reductions will be continued for at least the next thirteen years and have a very significant effect through the year 2010. (Edited author abstract) 9 refs.

## Diffusion

**093177 NUMERICAL SOLUTION FOR MASS TRANSPORT IN MEMBRANE-BASED DIFFUSION SCRUBBERS.** The Galerkin finite element method was used to develop a numerical model for the design of porous-wall diffusion scrubbers, devices which may be used as alternatives to diffusion denuders, and to selectively separate dissolved components from a liquid stream. It was found that the analytical P. Gormley-M. Kennedy solution for a tube with an ideally absorbing interior wall is appropriate for scrubbers characterized by a gas-liquid interface at the wall. However, the major conclusion of this work is that the Gormley-Kennedy solution is often inappropriate for application to diffusion scrubbers based upon a liquid-liquid interface at the wall. For such scrubbers, the unknown concentration boundary condition at the interior wall can be accounted for with the numerical solution, thus providing a design tool that has not been previously available. A set of penetration curves was generated for design purposes, and example applications are provided. (Author abstract) 25 refs.

## Evaluation

**093178 EVALUATION OF FINE PARTICLE WET SCRUBBERS.** A study was undertaken to reduce emissions for a calciner stack. Tests were conducted to characterize the particle size distribution, effluent loading, and chemical composition. Several methods for reducing emissions were evaluated. The source of the effluent was found to be due to some combination of: excessive mist carryover from a spraytower, flashing of high solids concentration quench liquid, poor flow patterns, a large quantity of fine particles, condensation of metal vapors, or gas phase reaction which formed fine particles. A series of studies were conducted to improve the operation of the spray tower. As only limited success was achieved with these methods several other control devices were evaluated. This article discusses (1) the methodology used to evaluate the cause of the effluent problem, (2) the principles followed in obtaining a representative slipstream, and (3) the performance of the three devices tested, along with parameters which affect performance. (Author abstract)

## Foundations

**093179 GRUENDUNG DER WAESCHER-STRASSE EINER RAUCHGASENTSCHWEFELUNGSANLAGE.** [Foundations for the Scrubber Line of a Flue Gas Desulfurization Plant]. German power generation companies are currently doing a great deal to prevent air pollution. A total of approx. 15 billion Deutschmarks has been invested in measures aimed at reducing SO<sub>2</sub> emissions from coal-fired power stations. Using the example of a lignite-fired power generation plant, this paper outlines the extensive structural measures required for this, in particular the foundations for the scrubber line. (Author abstract) In German.

Keitel, Helmut (Wayss & Freytag AG, Frankfurt am

Main, West Ger). *Bautechnik* v 65 n 1 Jan 1988 p 2-4.

## Industrial Applications

**093180 ENHANCEMENT IN INTERFACIAL AREA THROUGH PACKED VENTURI SCRUBBER.** Venturi scrubbers have gained greater importance as an equipment for air pollution control measures. The efficient contact of gases can be observed through high contact time and high interfacial area. To increase these parameters a H.D.P.E. wire noted packing of 96.8% porosity was inserted in a conical form in the diffuser section. A four fold increase in the interfacial area was obtained. (Author abstract) 11 refs.

Manthapurwar, N.S. (Natl Environmental Engineering Research Inst, Nagpur, India); Sonolikar, R.L.; Agarwal, A.L. *Indian J Environ Health* v 29 n 3 Jul 1987 p 242-246.

**Materials** See Also ELASTOMERS—Corrosion; FLUE GASES—Desulfurization.

**093181 TITANIUM...THE SOLUTION TO THE CORROSION PROBLEM IN FGD SCRUBBER SYSTEMS.** As pollution control equipment has become more sophisticated and the process streams closed to minimize effluents, the conditions that the materials of construction must withstand have become more severe. Environments that can be encountered in wet electrostatic precipitators and scrubbers include wet/dry conditions with high chloride levels at low pH and variable, often high, temperatures. Titanium and titanium alloys can meet the demands for a corrosion resistant material for construction of scrubber systems. Titanium has a history of excellent performance in acid chloride environments similar to those in a scrubber system and is cost competitive with other candidate materials of construction.

## Performance

**093182 PERFORMANCE OF A HYDRO-FILTER - MASS TRANSFER COEFFICIENT AND GAS-LIQUID INTERFACIAL AREA.** An experimental study of the effect of operating conditions on the performance of a hydro-filter (marble-bed scrubber) has been conducted. The overall volumetric mass transfer coefficient, K<sub>GA</sub>, remains constant while the gas flow rate changes in the stable operating regions but increases sharply in the region above the loading point, corresponding to a sharp increase in the total pressure drop of the hydro-filter. Since the gas flow is turbulent and the liquid flow is laminar under the present experimental conditions, the value of K<sub>GA</sub> is strongly dependent on the flow conditions of the liquid and its properties, while those of the gas have less effect. The performance of a hydro-filter as a mass transfer device is shown to be superior to other types of scrubbers although its main drawback is large pressure drop. (Author abstract). 18 Refs.

Uchida, S. (Shizuoka Univ, Hamamatsu, Jpn); Sumiyama, M.; Kamo, H. *Can J Chem Eng* v 66 n 4 Aug 1988 p 681-685.

## Protective Coatings

**093183 ORGANIC COATINGS IN SIMULATED FLUE GAS DESULFURIZATION ENVIRONMENTS.** Tests in simulated scrubber outlet duct environments show that the precise formulation of the coating as well as environment chemistry affect coating performance. In addition, entrapped air bubbles in the coating degrade coating reliability. The coatings included nine combinations of epoxy resins and amine hardeners, three vinyl esters, a polyester, a fluoropolymer, a urethane/asphalt, and an electrostatically sprayed, fusion-bonded epoxy. The testing demonstrated that chemical attack of the coating and corrosion of the substrate often depend on the pH and ionic makeup of the test solution. However, no single solution was consistently damaging to all coatings.

A correlation exists between ac conductance or dc resistance and the extent of substrate corrosion. The type of hardener affected the performance of epoxy resins - novolac and bisphenol A resins hardened with an aliphatic or cycloaliphatic amine provided the best protection.

## Pumps

**093184 SLURRY PUMPS FOR FLUE GAS DESULFURIZATION PLANTS.** Acid rain is a political issue. The evidence that damage is caused to the environment by sulfur dioxide deposition is significant. Slurry pumps operating in flue gas desulfurization plants have to be able to withstand some of the most hostile working conditions known. This article presents an insight into the demands on pumping equipment, materials and pump life and details a number of interesting applications.

De Ruijter, A. (Warman Int, Neth). *World Pumps* Jun 1987 p 172-174.

## Waste Disposal

**093185 SPRAY DRYER WASTE MANAGEMENT.** EPRI has conducted a number of studies to provide utilities with cost information on waste management for conventional wet scrubbing. Studies have characterized waste products; developed engineering designs for effective waste handling, disposal, and/or utilization; and estimated waste management costs. A study, completed in late 1986 evaluated spray dryer wastes. On a dollar-per-ton-disposed basis, spray dryer waste management costs were found to be higher than those for either conventional fly ash or scrubber sludge alone. Cost estimates for new and retrofit spray dryer applications must be revised upward from those produced earlier by EPRI. (Author abstract)

**093186 MODELS OF LABYRINTH SEALINGS FOR TURBOMACHINERY - PART I. FORMULATION OF THE PROBLEM AND STUDY OF GEOMETRICAL EFFECTS.** The nature of the flow in labyrinth seals is studied for the case where the flow is steady laminar and incompressible. The flow patterns and the pressure distributions within the labyrinths are obtained for different models of labyrinth in the absence of an imposed axial leakage velocity. Nine models were considered, the first three where the labyrinth casing or gland was grooved circumferentially with height-to-pitch ratios of 0.5, 1, and 2. The second family was studied when the shaft had grooves machined on its circumference with different values of height-to-pitch ratios, a third group of labyrinths with shafts stepped with the same height-to-pitch ratios was considered as above. The effect of geometrical configuration on the performance of the labyrinth sealing forms the starting point of the study of the problem in general. (Edited author abstract) 5 refs.

El-Gamal, Hassan (Alexandria Univ, Egypt); Awad, Taher; Saber, El-Sayed. *Modell Simul Control B* v 10 n 4 1987 p 41-52.

**093187 MODELS OF LABYRINTH SEALINGS FOR TURBOMACHINERY - PART II. THE LEAKAGE PROBLEM.** The effect of geometrical shape of models of labyrinth sealings on the amount of leakage losses through turbomachines has been investigated thoroughly in this work. Combinations of labyrinth models of practical importance have been considered here theoretically.

cally in great detail. It has been concluded that there exist some combinations of labyrinth models which give the optimum performance, that is, the minimum leakage for given pressure gradients. The choice of a specific model has been found to depend on the range of pressure gradient applied, whether small or relatively large. (Author abstract) 6 refs.

**093190 ANALYSIS OF ECCENTRIC ANNULAR INCOMPRESSIBLE SEALS: PART 1 - A NEW SOLUTION USING FAST FOURIER TRANSFORMS FOR DETERMINING HYDRODYNAMIC FORCE.** A new analysis procedure is presented which solves for the flow variables of an incompressible-flow annular pressure seal in which the rotor has a large static displacement from the centered position. The analysis begins with a set of governing equations based on a turbulent bulk-flow model and Moody's friction equation. No simplification of these bulk-flow equations are required for the solution procedure. Perturbation of the flow variables yields a set of zeroth and first-order equations. The zeroth-order equations (which model the large static displacement) are integrated by means of an efficient new method which employs Fast Fourier Transforms. (Edited author abstract) 19 refs.

**093191 ANALYSIS OF ECCENTRIC ANNULAR INCOMPRESSIBLE SEALS: PART 2 - EFFECTS OF ECCENTRICITY ON ROTORDYNAMIC COEFFICIENTS.** In a previous paper, a new analysis procedure was presented which solves for the flow variables of an annular pressure seal in which the rotor has a large static displacement (eccentricity) from the centered position. This paper (Part 2) incorporates the solutions from Part 1 to investigate the effect of eccentricity on the rotordynamic coefficients. The analysis begins with a set of governing equations based on a turbulent bulk-flow model and Moody's friction factor equation. Perturbations of the flow variables yields a set of zeroth- and first-order equations. After integration of the zeroth-order equations by means of the method described in Part 1, the resulting

zeroth-order flow variables are used as input in the solution of the first-order equations. (Edited author abstract) 2 refs.

**093194 STRESS FIELDS IN A COMPRESSED UNCONSTRAINED ELASTOMERIC O-RING SEAL AND A COMPARISON OF COMPUTER PREDICTIONS AND EXPERIMENTAL RESULTS.** A finite element stress analysis computer program, FEMALES (an acronym for Finite Element Mechanical Analysis of Large Elastic Strain), has been developed specifically for the analysis of large deformations in elastomeric materials. In this paper, the program is reviewed for use in elastomeric sealing applications. The principle of operation of the program is described, and its performance is compared with experimental and analytical results for the case of an O-ring compressed between flat plates. Two main methods for specifying elastic material properties are considered: firstly, an elaborate method which involves a range of measurements from elastomer specimens, and, secondly, another known as the neo-Hookean model, which only requires estimates of Young's modulus and the bulk modulus. In this particular application it was found that the two models gave similar results. This supports the use of the simpler model, since the materials data can be very readily obtained. The overall conclusion drawn from the work was that FEMALES is a workable system that produces results in good agreement with experiment. (Edited author abstract) 24 refs.

**093195 CONTACT PAIR SEALING MECHANISM IN AN END SEAL.** Efficient sealing and long life are the two main requirements which determine the design of end seals. These requirements together ensure minimum leakage through the end clearance and minimum wear of the contact pair over a long period of operation. To reduce leakage it is necessary to ensure that the reduction in fluid film thickness as a result of the load applied to the friction pair is such that boundary friction occurs. For certain friction conditions equations are available for assessing the fluid leakage. Research shows that with increasing specific loading of the friction pairs, leakage is reduced. 10 refs.

Golub, M.V. *Sov Eng Res* v 7 n 3 Mar 1987 p 19-21.

**093196 CONTACTING MECHANICAL SEAL DESIGN USING A SIMPLIFIED HYDROSTATIC MODEL.** While hydrostatic theory of mechanical face seal operation is well understood, there has always been some difficulty in applying this idea to the design of seals that contact. In this paper, a simple mixed friction model of seal load support is formulated. Surface roughness is an essential parameter. Mechanical contact load support and hydrostatic load support are both considered. Local support equilibrium is always satisfied. The minimum film thickness and leakage are found. Considering both fluid and mechanical contact friction, the total power consumption is found. The model works equally well for convergent or divergent films. This model is combined with both thermally - caused and pressure - caused radial taper effects using a simple relationship. Using very few algebraic equations, one can solve for the equilibrium operating conditions for practical seals. (Edited author abstract) 13 refs.

**093198 ALGEBRAISCHE BERECHNUNG VON INTEGRALEN KENNGROSSEN FUER DIE INKOMPRESSIBLE STROMUNG IN EINER LABYRINTHDICHTUNG.** [Algebraic Calculation of Integral Values for the Incompressible Flow in a Labyrinth Seal]. In an earlier work finite-difference computations and measurements had been performed in the model of a labyrinth seal. The Reynolds number of the shaft was  $Re = 5.04 \cdot 10^4$  and the Taylor number  $Ta = Re(s/R_1)^{1/2} = 1.77 \cdot 10^4$ , shaft was  $Re = 5.04 \cdot 10^4$ . For engineering applications pressure, mean circumferential velocity, kinetic energy of its fluctuations and its dissipation are estimated algebraically in the present contribution. This is done by means of the classical relations for the fully turbulent flow around a shrouded rotating shaft and a shrouded rotating disk. Additional measurements in the

range of  $1.3 \cdot 10^4 < Re < 10^5$ , i.e.  $4.4 \cdot 10^3 < Ta < 3.5 \cdot 10^4$ , confirm the validity of the algebraic formulae. In German. 19 refs.

**093199 SECONDARY SEALING.** While double and tandem seals provide the secondary containment needed for critical sealing applications, cheaper and less cumbersome alternatives are sought by many plant operators. A number of the major seal manufacturers have focused in recent years on developing both dry running and non-contact, or 'fully abeyant', standby arrangements. The Flexibox company's SBOP standby seal running on dry air has been developed with careful attention given to reducing the friction of sliding packings which has enabled low spring loads to be used. This, combined with wider faces and silicon carbide versus carbon faces, has allowed the necessary low wear rates to be attained. Tests, he says, have indicated lifetimes in the standby mode of over 16 000 hours. Other dry and non-contacting standby seals are also described.

**093200 EFFECTIVE USE OF BUFFER GAS SLEEVE-TYPE SEALS IN CENTRIFUGAL COMPRESSORS.** In this paper, the behavior of a buffer gas sleeve-type seal is explained on the basis of statistical physics. This is related to measurements made in an actual application with normal runout and vibration. Optimum utilization of this kind of seal in centrifugal compressors is discussed. It is concluded that a straight sleeve seal can be made more effective and efficient than the labyrinth seals that are usually used in such buffer seal applications. (Author abstract). 3 Refs.

**093201 TRANSIENT RESPONSE OF FLOATING RING LIQUID SEALS.** The design and analysis of pressure balanced seals are important to the designers and users of turbomachinery which require floating element seals. The design objective for compressor seals differs from that of the engineered pump seal but the common factor includes the ability to predict the dynamic response of the floating ring seal relative to the rotor shaft. Steady-state calculations can be used to study possible operating conditions for compressor designs, but they do not include accurate account of rotor shaft response and ring spin torque. In addition, engineered pump seal applications are such that the ring is expected to track shaft movement during start-up and shut-down transients when reduced pressures and leakage produce laminar flow sealing conditions. (Edited author abstract). 10 Refs.

**093202 DEVELOPMENT OF SEALANT SELF CIRCULATION 'VISCOSSEAL'.** When vapor is sealed with a liquid sealant of the same substance, gas ingestion takes place at the liquid-gas interface on one side (atmospheric side) of a pair of viscosseals. This ingested gas flows into the central cavity between the two viscosseals, and then a part of the ingested gas leaks into the sealed chamber through the viscosseal on the other side (turbine side). As one of the countermeasures for this type of gas leakage, a modified viscosseal with a self-circulating sealant loop has been proposed. The characteristics of the modified viscosseal are described in this paper. (Edited author abstract). 11 Refs.

## Fluid Dynamics

**093203 STUDY OF FACE SEALS WITH ECCENTRIC ROTATION.** We present the results of a theoretical study of the dynamics and flow of fluid in face seals. The expression for the leakage, obtained by solving the viscous fluid equations with account for the variable clearance in the face seal, shows that the centripetal fluid flow depends in considerable measure on the skew angle and the magnitude of the eccentricity in the friction pair. The obtained results are of significant importance for face seals of downhole electrical equipment. (Author abstract) 1 ref.

Griskin, E.N. *Sov J Frict Wear* v 8 n 2 1987 p 14-21.

**093204 SEALING MECHANISM OF ROTARY SHAFT LIP-TYPE SEALS.** In order to clarify the sealing mechanism of rotary shaft lip-type seals, the dynamic behaviors of the microasperities on the sealing surfaces and the triple interlines among air, oil and solid surfaces were observed through a hollow glass shaft with the aid of a microscope, an imaging television camera, and video tape recording. The recorded original pictures of the microasperity contacts were statistically analyzed after a digital image processing method was applied. As a result, several characteristic values were introduced which express the configuration of the contacting surfaces in terms of the distribution of the microasperities existing at the contacting surfaces of rotary shaft lip-type seals under dynamic conditions. Through the measurement of these characteristic values, models of sealing surfaces were proposed to characterize real microgeometries under nonleaking and leaking conditions of rotary shaft lip-type seals. In addition, it was confirmed that the theoretical sealing condition expressed by the models agreed well with the experimental one for real rotary shaft lip-type seals. **093205 EFFECTS OF ELASTIC DEFORMATION ON SEAL DYNAMICS.** The dynamic characteristics and stability of the annular pressure seal employed in pumps have been theoretically deduced with consideration of the effects of elastic deformation due to the high pressure difference. Turbulent flow is assumed in both circumferential and axial direction, and the deformation of the seal and the shaft is governed by the linear theory of elasticity. The results derived herein considering the elastic deformation are compared with the previously published author's results in the stiffness, damping, and add mass coefficients. (Author abstract) 7 refs.

**093206 NUMERICAL AND ANALYTICAL STUDY OF FLUID DYNAMIC FORCES IN SEALS AND BEARING.** A numerical model based on a transformed, conservative form of the three-dimensional Navier-Stokes equations and an analytical model based on 'lumped' fluid parameters are presented and compared with studies of modeled rotor/bearing/seal systems. The rotor destabilizing factors are related to the rotative character of the flow field. It is shown that these destabilizing factors can be reduced through a decrease in the fluid average circumferential velocity. However, the rotative character of the flow field is a complex three-dimensional system with bifurcated secondary flow patterns that significantly alter the fluid circumferential velocity. By transforming the Navier-Stokes equations to those for a rotating observer and using the numerical code PHOENICS-84 with a nonorthogonal body fitted grid, several numerical experiments were carried out to demonstrate the character of this complex flow field. ## Hydrodynamics

**093207 HYDRODYNAMICS OF RUBBER SEALS FOR RECIPROCATING MOTION, LUBRICATING FILM THICKNESS, AND OUT-LEAKAGE OF O-SEALS.** This paper gives the fundamentals of the hydrodynamics of rubber seals for reciprocating motion, introducing certain modifications that are aimed at availability of engineering practice and conformity with experiment. The inverse problem in the theory of hydrodynamic lubrication of a rubber seal has been related with the contemporary achievements in elastohydrodynamic lubrication of the contact with a roll made of a low elasticity modulus material. The experimental verification of the relationship which conditions height of the slot (lubricating film thickness) between the sealing ring and surface of the sealed element on material, geometrical, and exploitation parameters of the O-ring is a significant result of this research work. This dependence solves the problem of lubrication and leakage in the case of O-rings during the outstroke of the sealed element. (Author abstract) 8 refs.

Karaszewicz, Artur (Technical Univ of Warsaw, Warsaw, Pol). *Ind Eng Chem Res* v 26 n 11 Nov 1987 p 2180-2185.

**093208 HYDRODYNAMICS OF RUBBER SEALS FOR RECIPROCATING MOTION.** The author found that the techniques involved in determining the design of O-ring seals and their suitability for a particular purpose has been a somewhat inexact science. He gives an experimentally verified formula relating to the height of the lubricating film thickness between the O-ring and the sealed element, with the material of the O-ring, its geometrical parameters and the required operating conditions, which he considers may become the basis for designing O-ring seals. (Edited author abstract) 6 refs.

## Leak Detection

**093209 MEASURING SEAL LEAKAGE.** To address the need for accurate seal flow data a new tracer gas injection technique is under development for on-line seal leakage measurement. When developed, such a system would eliminate the difficulties of measuring seal clearance. Initial testing of such a system suggests that plus-or-minus 10 percent accuracy is possible, compared to 30% uncertainty in calculated methods. 5 refs.

McGreehan, William F. (Air Systems Design); Haaser, Fred G.; Sherwood, Laurence T. *Leading Edge (Evendale OH) Spring* 1987 p 30-35.

**093210 LEAKAGE CHARACTERISTICS OF STEPPED LABYRINTH SEALS (A CONTINUED REPORT, EFFECTS OF SHAPE FACTORS ON LEAKAGE RATE).** In this study, the effects on the leakage rate shape factors, such as relative position  $a_D/l$ , number of fin  $n$ , height of step  $h_2$ , depth of groove  $h_1$  and pitch  $l$ , thickness  $\delta$  and clearance of fin  $\epsilon$  are investigated in detail for stepped labyrinth seals (downward stepped type), which have a higher efficiency from the practical viewpoint, and their optimum shapes at both the stationary and rotating states are determined. The geometrical values for their optimum shapes are in those cases when  $h_2/l$ ,  $a_D/l$ ,  $h_1/l$ ,  $\delta/l$ , and  $l/\epsilon$  take the values around 0.2, 0.4 to approximately 0.5, 0.5 to approximately 0.6, 0.4 and 15, respectively. On the basis of these results, a method of predicting the leakage rate and the plan procedure are described. On the other hand, the present experimental

result is obtained by using a comparatively larger rotor to increase the peripheral velocity. (Edited author abstract) 5 refs. In Japanese.

**093211 SEMICONDUCTOR SEAL TESTING.** All international specifications agree that the sensitivities of fine and gross leak test methods must overlap. This is because many of the leaks that occur in semiconductor packages occur beyond the detection range of commonly used test methods. Up to 40 per cent of leak test failures may escape detection. The article describes several methods: gross leak test method; weight gain method; two step fluorocarbon leak detection; vapor detection systems; fine leak testing.

## Lubricants

**093212 LUBRICANTS AND THEIR EFFECTS ON SEALS.** Cooperation among component, sealing systems, and lubricant manufacturers is crucial to providing consumers the best seal-lubricant-component systems. Selection of a particular elastomer system for a sealing application is generally made as a balance of several factors: over all cost, operating temperature ranges, and anticipated lubricant types. Field failures due to use of replacement lubricants in a component which aggressively attach or swell the seal's critical elastomer element, are familiar to seal manufacturers. (Edited author abstract)

Anon. *Automot Eng (Warrendale Pa)* v 95 n 11 Nov 1987 p 79-83.

## Lubrication

**093213 FACE SEAL WITH CIRCUMFERENTIAL PUMPING GROOVES AND RAYLEIGH-STEPS.** This paper presents an analysis of a new noncontacting face seal with circumferential pumping grooves and shrouded Rayleigh-steps. The hydrodynamic lubricating film is maintained under rotation due to the Rayleigh-steps. If the low pressure side of the seal is filled with a fluid, the fluid can be pumped into the high pressure side through the circumferential pumping grooves until the shaft speed reaches a limit value. The experimental result confirms the theoretical prediction for the lubricating and sealing performances. Due to the high pumping ability in addition to the high stiffness of its hydrodynamic film, the seal can operate without wear and leakage for a high pressure fluid. **093214 CMMs RIDE HERD ON RAWHIDE'S QUALITY DRIVE.** Chicago Rawhide makes transmission seals, main-bearing seals and frontwheel seals to prevent loss and contamination of lubricants in autos, trucks, farm equipment and other vehicles. The seals range from simple, one-piece components multipart assemblies of metal and rubber. The company uses coordinate measuring machines (CMM) to provide the inspection capabilities for statistical process control.

Rakowski, Leo R. (Machine & Tool Blue Book, Wheaton, IL, USA). *Mach Tool Blue Book* v 82 n 12 Dec 1987 p 30-34.

**093215 SEALS FOR BIOREACTORS.** Vessels used for reactions involving biological changes and materials place special demands on mechanical seals; for example, preventing leakage into a bioreactor can be just as important as eliminating product escape. Careful design and a keen awareness of the consequences of inadequate performance are the keys to the effective sealing of a rotating shaft that penetrates the shell of a bioreactor. There

are several special considerations that the seal manufacturer has to take into account in such cases.

**093216 LIFE CYCLE EXPERT.** This case study illustrates the quality professional's role in knowing the product's entire life cycle, from raw materials to end user with regard to the functioning of a pharmaceutical seal manufacturing plant in Clearwater, Florida. The plant is highly automated, with each worker tending from one to ten machines. The three primary materials used to make seals are here examined as to how they are released to production and how this might be done in the future. In addition, the role of traditional inspectors is examined in two manufacturing departments. The general role of quality professionals, along with that of the hourly quality work force, is reassessed. Product life cycle is evaluated relating to new products, changing current product, and raw materials. 3 refs.

**093218 MATERIAL PERFORMANCE FOR SEALS AND PACKAGINGS.** The day of asbestos cord and simple packings to provide a seal in pumps and other machinery is almost past. This article shows how the demand of designers for glands and packings to withstand high temperatures, aggressive fluids and higher performance, have been met by the use of composite and sometimes exotic materials, together with sophisticated designs employing fillers and reinforcement of various kinds. He makes the important point that co-operation between the mechanical designer and the seal specialist is essential at an early stage if satisfactory performance is to be achieved.

Bayliss, Neil (Mercia Rubber Ltd). *World Pumps* Jul 1987 p 195-196.

**093219 FLUID SEALING WITHOUT ASBESTOS.** The hazardous effect of the use of blue asbestos is now well known and strenuous efforts are being made in many different fields to develop suitable alternatives. This article shows how this trend has affected the manufacturers of gaskets and packings, for which no one substitute has proved satisfactory for all occasions.

McClure, Bill (TBA Industrial Products Ltd). *World Pumps* Jul 1987 p 198-199.

**093220 STATUS OF RECENT MECHANICAL SEALS.** The application of SiC as the material of seal faces is opening new pages in mechanical seal technology. In this paper, various types of SiC and their characteristics are described, and two successful examples of SiC application at ultrahigh PV values are reported. These two examples indicate that progress in mechanical seal technology is rapidly extending its application possibilities. (Edited author abstract) In Japanese. 3 refs.

Fujita, Takuya (Eagle Industry Co, Sakado, Jpn). *J Jpn Soc Lubr Eng* v 32 n 12 1987 p 850-855.

**093221 RAYLEIGH-STEP FACE SEAL WITH REVERSE STEPS.** This paper presents a new hydrodynamic seal, in which the pressure drops caused by the reverse steps reduce the hydrodynamic film force, while

they scarcely affect the film stiffness if the step recesses are deep enough. Thus, the clearance is controlled at high-speed operation. The numerical analysis clarifies that the leakage flow rate of the seal is less than a critical value over the entire range of rotating velocities. The critical leakage flow rate which corresponds to a zero hydrodynamic film force condition is determined by the seal face design, and it is independent of the balance ratio. If the seal operates at a relatively low balance ratio, a hydrodynamic lubricating film is formed at a low velocity. In addition, leakage is limited at a high velocity. The experimental results confirm that a seal with reverse steps shows excellent performance over a wide range of rotating velocities. (Author abstract) 3 refs.

**093222 POLYURETHANE ELASTOMERS AS HYDRAULIC SEAL MATERIAL.** The availability of the diisocyanate paraphenylene diisocyanate (PPDI) and cyclohexyl diisocyanate (CHDI) has made possible the synthesis of thermoplastic polyurethanes (TPU's) which have greater thermal stability than previously obtainable as predicted from their DMTA thermograms. The ability to combine elevated temperature service with the unique strength and wear resistant properties of polyurethane, together with the automation made possible by the thermoplastic injection molding is considered to represent an advance in current seal materials. This paper describes the special synthesis and formulation of TPU's based on PPDI and CHDI together with a spectrum of the strength properties used to judge them as potential seal elastomers. Some of these TPU elastomers possess tensile strengths of 50 MPa and compression set values of <25% obtained by using special post-curing techniques. DMTA data is used to predict these TPU's responses to elevated temperatures. (Author abstract) 2 refs.

Hepburn, C. (Loughborough Univ of Technology, Loughborough, Engl). *Cell Polym* v 6 n 5 1987 p 51-66.

**093223 GRAPHITE AND CARBON FIBERS FOR COMPRESSION PACKINGS.** Graphite exhibits better thermal and electrical conductivity, greater resistance to mechanical wear, and lower thermal expansion. On the other hand, carbon is superior to graphite in resistance to fracture and abrasion from suspended particles. Fibers and yarns of carbon and graphite are available in various strengths ranging from 20×10<sup>6</sup> psi to greater than 50×10<sup>6</sup> psi modulus. Carbon and graphite fibers and yarns have gained wide acceptance in the packings and seals industry because of their thermal and chemical resistance. Manufacturers of mechanical packings provide carbon and graphite in various forms which include braided yarns, twisted yarns, and rovings. The constructions are normally impregnated or coated with lubricants to enhance fluid blocking and extend chemical resistance.

## Measurements

**093226 EXPERIMENTS ON DYNAMIC STIFFNESS AND DAMPING OF TAPERED BORE SEALS.** Stiffness and damping were measured in tapered bore ring seals with air as the sealed fluid. Excitation was provided by a known unbalance in the shaft which rotated in the test seals. Results were obtained for various seal supply pressures, clearances, unbalance amounts, and shaft speeds. Stiffness and damping varied little with unbalance level, indicating linearity of the seal. Greater variation was observed with speed and particularly supply pressure. A one-dimensional analysis predicted stiffness fairly well, but considerably overestimated damping. (Author abstract) 11 refs.

**093227 RINGING PHENOMENA OF MECHANICAL SEALS.** Ringing phenomena in mechanical seals of automotive water pumps are divided into two types, according to the mechanism of their occurrence. One is caused by sealed liquid boiling between, or near, the sliding surfaces. The ringing is observed only when sealing conditions cause the sliding surfaces to reach a higher temperature than the boiling point of the sealed liquid and can be prevented by improving the heat-transfer capacity of the seal. The other is caused by stick-slip between the sealing surfaces. In general, the stick-slip motion is generated by the interaction between vibration and lubrication characteristics. From the viewpoint of the vibration characteristics, increasing the stiffness is effective in preventing the ringing. On the other hand, as to the lubrication characteristics, the negative slope of the torque-speed curve should be as weak as possible in low speed ranges. (Edited author abstract). 12 Refs. **093231 IMPROVING THE RELIABILITY OF CUFF-TYPE SEALS.** We present the results of experimental studies made to improve seal reliability and reduce leakages of the sealed medium. We examine two different cuff constructions and techniques that make it possible to markedly reduce the contact friction torque with simultaneous reduction of the sealed medium leakage. The studies are performed using the same technique, which makes it possible to obtain comparable results and present recommendations on the application of these seals. (Author abstract) 6 refs.

**093232 SELECTION OF SEAL CONSTRUCTION FOR CLOSURES OF VESSELS WHICH OPERATE UNDER CONDITIONS OF CYCLIC VARIATION IN PRESSURE AND TEMPERATURE.** The object of this work was to show how, on the basis of classification and analysis of existing sealing units, a promising construction is selected, and to examine the directions of studies which are necessary to introduce it. The classification suggested includes nine groups of criteria which characterize methods of ensuring hermeticity, mechanism of operation, and

constructional make-up sealing elements. Using the proposed classification, advanced construction characteristics have been selected, and an analysis of the operation of existing sealing unit constructions and auxiliary devices has been performed for conditions of cyclic loading by pressure or temperature. 9 refs.

**093233 SAFEGUARDS SEALS ACTIVITIES UPDATE.** Ongoing commercial developments, some Department of Energy (DOE) contractor-initiated developments, and the desire to standardize seals and procedures stimulated the establishment of a seals task force to assess the current seals situation, develop reference material to assist in standardization, and recommend appropriate long-term activities. This paper summarizes the results of the task force effort and briefly discusses some of the more recent domestic seals developments. (Author abstract) 3 refs.

**093234 FACE WAVINESS OF SPLIT SEALS.** Face waviness influences solid-to-solid contact and fluid pressure distribution, and controls fluid leakage of mechanical seals. Using Fourier series, the effects of misalignment on waviness can be studied. Analytical results show that the third cosine harmonic is the lowest-order harmonic not affected by misalignment. Three face height traces of a split seal ring were taken and analyzed. They were taken along the same waviness measurement track, but at different degrees of misalignment. Though their 'peak-to-valley' magnitudes change significantly, the third-harmonic cosine coefficients remain constant, which substantiates the analytical finding. (Edited author abstract). 1 Ref.

## Ultrasonic Applications

**093235 ULTRASONIC IDENTITY DATA STORAGE AND ARCHIVAL SYSTEM.** Ultrasonic seals are being used to determine if an underwater stored spent fuel container has been compromised and can be used to determine if a nuclear material container has been compromised. This paper has described a system designed to conveniently handle ultrasonic seal signature information. The concept centers on a main data base being located at IAEA headquarters, with the necessary interface to allow for the transfer of data using the SPAR bubble cassette. This system was installed at the IAEA in November, 1986, and is presently undergoing evaluation. (Edited author abstract) 5 refs.

## Vibrations

**093236 EFFECT OF TORSIONAL VIBRATIONS ON THE LEAKAGE FROM MODELS OF LABYRINTH SEALS.** The theoretical treatment of the oscillatory fluid motion resulting from the torsional vibration of a rotating shaft having labyrinth seals models of several geometrical configurations and for different values of the axial leakage velocity is considered here. Solutions for the so-called steady streaming components to order  $S^{-2}$

(S=the Strouhal or the frequency number) are presented in some detail. It was found here that the torsional vibrations may improve the performance of the labyrinth seal, have no effect and may worsen the performance depending on the model of the labyrinth seal selected. (Author abstract) 9 refs.

## Wear

**093237 MECHANISM OF HYDROGEN WEAR OF AUTOMOTIVE AND TRACTOR ENGINE WATER PUMP FACE SEALS.** We present the results of spectral, durametric, electron-microscope, and roentgenographic studies of water pump bearing face specimen microvolumes in contact with the sealing washer. It is shown that the process of destruction of the near-surface layers of the bearing face material is associated with the onset of tensile stresses due to significant increase of the hydrogen content in the hydridophylic zone. We identify the periodic nature of the change of the hydrogen concentration and the wear rate in time. We construct a mathematical model of the water pump bearing face hydrogen wear process; this model satisfactorily describes the experimental data. (Author abstract) 9 refs.

## SEAPLANES

### Design

**093238 SOME THOUGHTS ON POWER-AUGMENTED-RAM WING-IN-GROUND (PAR-WIG) EFFECT VEHICLE.** The PAR (power-augmented-ram) WIG (wing-in-ground) effect vehicle is highly promising as an overwater commuter transport vehicle. Three important requirements, the PAR effect, the ability of OGE (off ground effect) flight, and the ability of automatic IGE (in ground effect) flight, are described. Many useful materials for designing WIG effect vehicles are presented. New concepts are proposed which contain some new devices. The ability of "stick-free" IGE flight is especially desirable, and hence the phugoid mode should be suppressed sufficiently. (Edited author abstract). 13 Refs.

**093239 BUBBLE MOTIONS IN SEA WATER.** This paper considers one aspect of the problems associated with bubbles in the wake of a surface ship. A method which has been developed for calculating the evolution and transport of bubbles is described. Results which were obtained with this method are presented and are compared with the limited experimental data which are available. Generally good agreement was found between the numerical and experimental results. Several areas are noted where further research is indicated. (Author abstract) 11 refs.

**093240 KINETICS AND MECHANISM OF HYDROGEN SULFIDE OXIDATION IN SEA WATER.** Oxidation of hydrogen sulfide in sea water occurs mainly at the boundary of the aerobic and anaerobic zones, in the layer of coexistence of hydrogen sulfide and oxygen (C

layer). Hydrogen sulfide zones have begun to form as a result of anthropogenic influences on the shelf of the Black Sea. A prediction of the dynamics of the C layer has become an extremely urgent problem in connection with the threat to fisheries, development of agriculture, and recreational value of the Black Sea coast. The key problem when constructing appropriate predictive models for calculating the dynamics of the C layer is knowledge of the kinetics and mechanism of hydrogen sulfide oxidation in sea water and the dynamics of the mass transport of oxygen and hydrogen sulfide. This paper discusses oxidation agents and products, mathematical models and conditions of applicability, and other aspects of the subject. 42 refs.

**093241 ONE-DIMENSIONAL MODEL OF GAS EXCHANGE BETWEEN THE OCEAN AND ATMOSPHERE.** Discussed are the main processes which condition gas transfer through the boundary layer of water. With the aid of the equation of balance of turbulent energy we estimated the profile of the coefficient of turbulent diffusion in the viscous sublayer. We obtained a one-dimensional equation of orbital motion in a system of rest of the free surface for a flat wave with small curvature. A conclusion is formed about the independence of the amplitude of this movement from wavelength for gravity waves. Within the framework of the one-dimensional model of advective-diffusion transfer we studied the contribution of wave movement to gas exchange. It is shown that with a windspeed of 2-7 m/sec the dependence of gas exchange velocity on wind speed is close to linear. (Author abstract) 17 refs.

Degterev, A.Kh. *Sov Meteorol Hydrol* n 3 1987 p 99-102.

**093242 STABILITY AND DECAY OF FOAM IN SEA WATER.** Surface foam is produced by the entrainment of air in the form of small bubbles at and just beneath the water surface during white-capping, when steep waves break, and when a displacement ship moves through the water. The residence time of a single- or multi-layer foam at the surface depends on the stability of the bubbles in that layer. This paper presents the results of a study which examined the influence of salt content on the foaming ability of water and on the stability of a three-dimensional foam produced by blowing air through controlled laboratory samples of simulated sea water and a sample of sea water obtained from an Atlantic coastal site. The results clearly show that varying the salt content of a clean water sample between 0 and 16 ppt significantly influences its foaming ability and the corresponding stability of a layer of surface foam. (Edited author abstract) 32 refs.

**093245 KADMIUMIN, LYLJYN JA KUPARIN PITOISUDET JA SITOUTUMINEN ORGAANISEEN MATERIAALIIN ITAMEREN MERIVEDESSA JA SEDIMENTISSA.** [Concentrations of Cadmium, Lead and Copper and Binding to Organic Matter in Water and Sediments of the Baltic Sea]. Anodic stripping voltammetry (ASV) is particularly suitable for trace metal analyses of sea water. In addition to total metal concentrations, the method allows the degree of complexation of trace metals to natural organic material to be determined. In the Gulf of Bothnia and the Gulf of Finland, the concentrations of cadmium and copper are similar to those in oceanic surface water, while the concentration of lead is somewhat higher. About half of the copper is bound to dissolved organic matter. (Edited author abstract) 37 refs. In Finnish.

**093246 INVESTIGATION OF THE MODIFIED FOULING INDEX AS A TEST FOR PLUGGING POTENTIAL OF PRETREATED SEAWATER.** The pretreatment of raw seawater is necessary to reduce the fouling of reverse osmosis membranes and increase run length. To measure the plugging potential of pretreated feedwater, the modified fouling index was tested using both control suspensions and pretreated seawater. The defining equation was found to adequately describe the process. By distinguishing between the various filtration mechanisms, the modified fouling index was found to be more precise than other plugging indexes. A scheme is presented for the in situ, computer controlled measurement of the modified fouling index. (Author abstract) 16 refs.

**093247 HYDROTHERMAL CH<sub>4</sub> BETWEEN 12°N AND 15°N OVER THE MID-ATLANTIC RIDGE.** Hydrothermal effluents enriched in gases such as helium, hydrogen and methane have been found outgassing from mid-ocean ridge zones, crustal rifts, volcanoes and other areas of tectonic activity. Although methane is not conservative in seawater, its analysis on board ship can be used qualitatively or semi-quantitatively to locate hydrothermal fields as a cruise progresses. Between 12° and 15°N over the Mid-Atlantic Ridge, CH<sub>4</sub> anomalies (up to 44 nl l<sup>-1</sup>) in the water column reveal the presence of plumes originating from hydrothermal discharge. The large amplitude of the CH<sub>4</sub> anomaly at one station (Hy-36) integrated over more than 1000 m, reflects a large CH<sub>4</sub> input and thus extensive hydrothermal activity in this slow spreading section similar to inputs from fast spreading sites like the East Pacific Rise. (Author abstract) 50 refs.

**093248 pH OF THE WATER OF THE BLACK SEA.** Materials of five expeditions were used to study the spatial distribution of pH in the water of the Black Sea. Anomalies of the vertical distribution of pH, not described in the literature, and the major factors determining the structure of the vertical distribution of pH in the 0-300 m water layer are established. A mathematical model of the development of the vertical structure of the pH in the layer of coexistence of  $O_2$  and  $H_2S$  is constructed which considers hydrodynamic factors and the process of oxidation of hydrogen sulfide. ## Beryllium Determination

**093251 DISTRIBUTION OF  $^{10}Be$  AND  $^9Be$  IN OCEAN WATER.** The vertical distributions of  $^{10}Be$  and  $^9Be$  have been measured at several locations in the Pacific and the North Atlantic. The results from the Pacific show that both isotopes exhibit nutrientlike profiles resulting from participation in the cycling of marine particulates. The  $^{10}Be/^9Be$  ratios from the different stations vary from  $1$  to  $3 \times 10^{-7}$  in the mixed layer but tend towards a value close to  $1.1 \times 10^{-7}$  in the deep ocean. Profiles from North Atlantic stations show a lower deep-water  $^{10}Be/^9Be$  ratio of about  $6 \times 10^{-8}$ . (Author abstract) 16 refs.

## Environmental Testing

**093257 MULTI-SEDIMENT-TRAP STUDY ON THE TEMPORAL AND SPATIAL VARIABILITY OF POLYCYCLIC AROMATIC HYDROCARBONS AND LEAD IN AN ANTHROPOGENIC INFLUENCED ARCHIPELAGO.** Sixteen sediment traps have been used to collect seston for more than 8 months to study the spatial and temporal distribution of 18 PAH compounds and lead in the Stockholm archipelago (Baltic Proper). Concentrations and especially fluxes exhibit a steep logarithmic decline with distance from urban areas. PAH concentrations and fluxes are higher during the winter-spring period than during the summer due to increased emissions, more extensive washout of land-deposited PAH during snow melting, and resuspension caused by nonstratified water conditions and mixing zone effects. Results indicate that air-transported black carbon particles from a variety of 'nonpoint' pollution sources are the probable main carriers of PAH in combination with particles from direct runoff for the stations in the immediate surroundings of the urban area. (Edited author abstract). 76 Refs.

**Filtration** See Also SANDSTONE.

**093258 CROSS-FLOW MEMBRANE FILTRATION OF SEA WATER.** Large tubular membranes, developed for the continuous treatment of hazardous liquid wastes, particularly those containing heavy metals, at rates up to  $100m^3/h$ , have been evaluated over the past two years for use with sea water, large volumes of which are required for injection into offshore oil reservoirs. Required quality of water is typically 95-98% removal of particles greater than  $2\mu m$ , with volumes of water up to  $2,600m^3/h$ . Although the 'dead-end' separation efficiency of the coarsest membranes was probably adequate for this sea water application, in the cross-flow mode the active filtration surface is believed to be 'dynamic membrane' formed by deposition of solids on the membrane surface. Under these conditions, the separation efficiency of even the coarsest membranes was very high. (Edited author abstract) 5 refs.

## Heat Transfer

**093259 MODELLING SEA SURFACE TEMPERATURE RISE RESULTING FROM INCREASING ATMOSPHERIC CARBON DIOXIDE CONCENTRATIONS.** Concern over the role of the oceans in a warming world, likely to result from increasing atmospheric carbon dioxide, has prompted analysis using simple models. Results from two recent, independent studies using a simple box-diffusion model suggest that over the last 130 years, observations and models are not in disagreement. Although a diffusive deep ocean was indeed included in this simplistic model, it is suggested here that the resulting ocean model offers an oversimplistic view of the oceanic contribution to the overall global atmosphere-ocean climate system and that it is necessary to add a convective capability to the water column. Using this approach it is suggested that, on a timescale of a century, the sea surface

temperature increase is likely to be less by a factor of at least 3 than that previously forecast. (Author abstract) 26 refs.

## Ion Exchange

**093260 THOROUGH SOFTENING OF SEA WATER BY STAGED-COUNTERCURRENT Na-CATION TREATMENT.** The possibility is investigated of thorough softening of Caspian Sea water by staged-countercurrent (s-c) Na-cation treatment. A method is developed for evaluating the feasibility of regeneration of the second stages of s-c filters with the spent regeneration solution of the preceding regeneration. Empirical formulas and regression equations are derived to describe the effect of the principal factors on the technological indices of secondary softening. The optimal ratio is determined for volumes of media of s-c filter stages, providing placement of 10-15% of the total media in the second stage. (Author abstract) 5 refs.

Abdullaev, K.M.; Agamaliyev, M.M.; Krikun, M.M.; Davydov, G.M. *Sov J Water Chem Technol* v 9 n 6 1987 p 83-87.

## Mass Transfer

**093261 CONCERNING A MECHANISM OF SALT TRANSFER IN A STRATIFIED FLUID.** A two-phase model of unsteady salt transfer is considered for a fluid consisting of turbulent spots and laminar interlayers. A relation is proposed for the dependence of the turbulent flow on the difference between the salt content in the spots and the interlayers. Estimates of the value of the proportionality coefficient are obtained for the salt transfer intensity and the salt boundary motion velocity for typical conditions of existence of the salt-water and fresh-water lenses in the ocean. (Edited author abstract) In Russian. 10 refs.

## Optical Properties

**093262 INTENSITY OF LIGHT REFLECTED FROM A SEA SURFACE.** A study is made of the reflection of light from a rough sea surface with allowance for single and double reflection. Detailed consideration is given to the brightness distribution in the vicinity of a caustic, i.e., in a domain where the geometric-optic approximation can not be applied. An explicit expression is found for the parameter that determines the reflected light distribution in the caustic zone. The total energy flux within the caustic zone is estimated. Concrete evaluations are presented for a sinusoidal surface. (Edited author abstract) In Russian. 8 refs.

Shifrin, K.S.; Gardashov, R.G. *Izv Akad Nauk SSSR Fiz Atmos Okeana* v 23 n 4 Apr 1987 p 415-422.

**093263 FLUCTUATIONS OF THE INFRARED RADIATION OF A ROUGH SEA.** On the basis of a stochastic facet model of a rough sea surface, a general expression for the variance of the infrared sea brightness is obtained. Convenient formulas are presented for applied calculations. Examples of calculations for the 10- $\mu$ m wavelength are presented. A physical interpretation of the results obtained is given. (Edited author abstract) In Russian. 14 refs.

**093264 RELATION BETWEEN OPTICAL TRANSFER FUNCTION AND NATURAL LIGHT FIELD IN THE SEA OR ATMOSPHERE.** In this paper relationship between the optical transfer function of sea water and the distribution of natural radiance field in the sea is

simply and directly determined based on the transform model of the sea-radiance transfer. The variance of the angle spectrum of the sea radiance field is analysed. A new simple method of estimating the distribution of the sea radiance field and measuring the optical transfer function of the sea water is proposed. The method is perfectly suitable for the atmospheric circumstances. (Author abstract) 11 refs. In Chinese.

Liu, Zhishen (Shandong Coll of Oceanography, China); Huang, Xiaosheng; He, Mingxia; Zhang, Zhiming. *Guangxue Xuebao* v 7 n 8 Aug 1987 p 707-713.

**093265 ZOOPLANKTON GRAZERS AS TRANSFORMERS OF OCEAN OPTICS: A DYNAMIC MODEL.** A model was developed, based on data collected in the Southern California Bight region, to assess the effect of zooplankton grazing on the attenuation of light due to suspended particles. Diel vertical distribution and grazing activity of the principal zooplankton grazers in the coastal waters of southern California were studied during mid-March, 1986. Model parameters are temperature, particle doubling rate, particle size-frequency distribution, zooplankton grazing efficiency and zooplankton size-frequency distribution. With parameters at their standard values, the diffuse attenuation coefficient,  $K_d$ , remains approximately constant, decreasing by only 3.5% in one 24-h cycle. The model is most sensitive to changes in temperature and, secondly, to changes in the abundance of grazers. Additional aspects of the subject are discussed. (Edited author abstract) 82 refs.

**093266 EMISSIVITY OF PURE AND SEA WATERS FOR THE MODEL SEA SURFACE IN THE INFRARED WINDOW REGIONS.** Emissivity of pure and sea waters for the model sea surface is tabulated as a function of the zenith angle of observed radiation ( $\theta$ ) and the surface wind speed in the infrared window regions, 3.5-4.1  $\mu$ m and 8-13  $\mu$ m. The sea surface is simulated by many facets whose slopes are changed according to the isotropic Gaussian distribution with respect to surface wind. Emissivity is also computed for the plane surface condition. Computational results show that 1) emissivity decreases slowly with the increase of  $\theta$ , 2) little effect of the surface wind is noted on emissivity for  $\theta \leq 30^\circ$ , whereas this effect greatly appear for  $\theta \geq 70^\circ$ , and 3) relative difference of emissivities between pure water and sea water is less than 0.1% within  $\theta = 50^\circ$  for wind speed less than 15 m/s. Finally, the corresponding apparent temperatures are also examined. (Author abstract) 10 refs.

## Phase Equilibria

**093267 PHASE EQUILIBRIA IN THE Na, K, Mg, Ca/SO<sub>4</sub>, Cl-H<sub>2</sub>O SYSTEM AT 25°C.** The structure of the diagram of phase equilibria in the Na, K, Mg, Ca/SO<sub>4</sub>, Cl-H<sub>2</sub>O six-component system at 25°C was investigated by the translation method. The presence of 41 sixfold nonvariant points was established, of which 33 are formed by straight-through translation and one is formed by unidirectional translation. Seven nonvariant points were established for the outlined trisaturation fields of solid phase in the region of the sixfold composition. A schematic structure of the acranite fragment of the investigated system is presented. (Author abstract) 12 refs.

## Radioactivity

**093268 INFLUENCE OF THE ARRIVAL OF RADIOACTIVE INDUSTRIALLY CONTAMINATED NORTH SEA WATER UPON THE RADIATION CONDITIONS IN THE BALTIC SEA.** The present work is a continuation of the author's preceding research on the radiation influence which North Sea waters contaminated by the effluents of the West European radiochemical plants have upon the conditions in the Baltic Sea. It was established by these investigations that practically the entire water area of the Baltic Sea is covered by industrial radioactive contamination to various extents. As in the past years, the highest levels of the industrial contamination are observed in the Southwestern part of the Baltic Sea. It follows that the <sup>134</sup>Cs which is missing in the global source is a much better radioactive indicator of industrial radioactive contamination than <sup>137</sup>Cs which enters into the sea water as precipitant from the atmosphere as well as via river water. 12 refs.

**093270 SOURCES OF RADIOACTIVITY IN THE OCEAN ENVIRONMENT: FROM LOW LEVEL WASTE TO NUCLEAR POWERED SUBMARINES.** This paper summarizes both natural and man-made radioactivity in the marine environment. Radioactivity occurs naturally in both the sea water and in the ocean sediment. Radioactivity in the sea water is fairly uniform geographically and is dominated by the naturally occurring isotope K (potassium-40). Unlike sea water, sediment radiation levels vary with sediment type and location. The primary source of natural radiation in the sediment results from deposition of insoluble thorium isotopes formed by the decay of water-soluble uranium. Man-made sources of radioactivity arise from, in descending order of importance: sinking of two U.S. and two Soviet nuclear submarines; fallout from nuclear weapons testing; dumping of primarily British and American low-level nuclear waste; and dumping of reprocessing plant radiated effluents from the British Windscale facility and other European and Indian reprocessing facilities. (Author abstract). 6 refs.

**Remote Sensing** See Also **OCEANOGRAPHY—Currents.**

**093271 COVER: CIRCULATION PATTERNS IN AVHRR IMAGERY.** AVHRR data have been used to study sea surface temperatures (SSTs) in the north east Atlantic and around the eastern coast of Scotland in an attempt to examine the development of circulation patterns in these waters. It is shown that within the Rockall Trough mesoscale eddies appear to dominate the mixing process allowing the transfer of heat, salt and nutrients between respective water bodies. Cyclonic eddies are most prevalent, as is to be expected in the Northern Hemisphere, but some anti-cyclonic activity is also evident. Differences between satellite-derived and buoy temperatures were of the order of 1.0 deg C and this error is thought to be due to a combination of the positional accuracy of the rectification algorithms, possible surface skin and wind effects, and the global nature of MCSST (Multi-Channel Split Window) algorithms together with the inherent problem of identifying a point buoy measure-

ment with an average satellite value. 5 refs.

**093272 EFFECT OF DISSOLVED 'YELLOW SUBSTANCE' ON THE QUANTITATIVE RETRIEVAL OF CHLOROPHYLL AND TOTAL SUSPENDED SEDIMENT CONCENTRATIONS FROM REMOTE MEASUREMENTS OF WATER COLOUR.** The effect of the dissolved 'yellow substance' on the quantitative retrieval of chlorophyll and suspended sediment concentrations from remote measurements of water color, has been investigated through a sensitivity analysis applied to theoretical simulations. Two different models for yellow substance absorption, derived from experimental observations, have been used in the computation. The results obtained showed important effects, leading to the conclusions that the presence of yellow substance must be taken into careful account in the process of inferring water composition for its color signature. (Author abstract) 21 refs.

## Sampling

**093276 UPTAKE OF CALCIUM AND MAGNESIUM FROM THE ARABIAN GULF WATER ON PLASTIC AND GLASS SURFACES.** The uptake of  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  from the Arabian Gulf water on walls of plastic and glass bottles was followed at room temperature for contact times up to 360 h. Both ions are physically

adsorbed in two distinct species, which can be leached out by water and acid elution, successively. The amounts adsorbed are too little to be of practical interest. Both plastic and glass bottles can be safely used to collect and store seawater samples. (Author abstract) 7 refs.

**093277 INCIDENCE OF YEASTS IN COASTAL SEA WATER OF THE ATTICA PENINSULA, GREECE.** Coastal sea water from 15 locations around the Attica peninsula, Greece, were collected and analyzed for the presence of yeasts on three occasions during 1984. Yeast cell densities ranged from 30 to 1020 CFU 50 ml<sup>-1</sup>. There was a marked increase in yeast cell densities during the summer months. A total of 30 yeast species were recorded, single sampling stations yielding from 8 to 27 species. Qualitative differences between sites were consistent throughout the sampling period. Potentially pathogenic species, often in high numbers, were recorded from many stations, the most common being *Rhodotorula* spp, *Candida* spp, and *Torulopsis glabrata*. (Edited author abstract) 23 refs.

## Surfaces

**093278 MODELING OF THE SEA SURFACE FOR DAYLIGHT IMAGERY STUDIES.** Plastic-coated paper is shown to possess reflectivity characteristics quite similar to those of the surface of water. This correspondence has been used with a conversion factor to model a sea surface by means of plastic-coated paper. Such a paper model is then suitably illuminated and photographed, yielding physically simulated daylight imagery of the sea surface under controlled conditions. A simple example of sinusoidal surface simulation is described. 5 refs.

Naidu, P.S. (Indian Inst of Technology, Bangalore, India); Reddy, Y.V. *IEEE J Oceanic Eng* v 13 n 3 Apr 1988 p 81-83.

**093279 LASER SEA SURFACE SENSING FROM AN AIRCRAFT.** One can use the statistics of the flashes produced by a narrow laser beam scanning over the sea in sensing the characteristics of the small-scale waves and determining the wave spectrum. Theoretical studies on the statistical characteristics of this random sequence have taken the sea surface as frozen, which is justified if the speed is  $v_c \gg c$ , where  $c$  is the characteristic speed of the surface waves. Here the authors give a method of calculating these characteristics with allowance for the wave motion, where experiments on that basis are analyzed. 5 refs.

**093280 METHODOLOGY FOR AN OPERATIONAL MONITORING OF REMOTELY-SENSED SEA SURFACE TEMPERATURES IN INDONESIA.** Operational sea surface temperature (SST) monitoring was tested with the study of large-scale SST features in Indonesia from July 1981 to June 1985. Digital data were provided by digitizing 208 weekly SST charts of NOAA-NESS. The pixel size corresponded to 1°15' longitude and latitude. These data displayed a 0.5 deg K r.m.s. error compared with 1985 in situ measurements. Iterative interactive factorial analyses combined with a parallelepiped classifier as a clustering technique enhanced the SST spatio-temporal features. The study area was divided into zones in which pixels had similar SST profiles and dates of occurrence of thermal anomalies were pointed out. Sea fronts and upwellings were mapped through spatio-temporal analyses of thermal gradients.

This study stresses the possibility of operational SST monitoring for Indonesia, allowing simple data manipulation with hardware easily maintained locally. (Author abstract) 20 refs.

## Thermodynamics

**093281 ESTIMATION OF ION PRODUCT OF WATER IN SEA WATER.** The equations of Sweeton, Mesmer, and Baes, of Marshall and Mesmer, and of Marshall and Franck, which were found useful in estimating the ion product of pure water at different temperatures and pressures, have now been applied for predicting the ion product of water in sea water at 0 and 25°C and up to 1000 bar pressure. By introduction of the density of sea water at a given pressure, the equation of Marshall and Franck describes some reliably calculated values for the ion product of water in sea water. The equation of Sweeton, Mesmer, and Baes with an added density relationship based on the equation of Marshall and Franck also provides these values. (Author abstract) 8 refs.

## Trace Analysis

**093282 DIRECT DETERMINATION OF DISSOLVED COBALT AND NICKEL IN SEAWATER BY DIFFERENTIAL PULSE CATHODIC STRIPPING VOLTAMMETRY PRECEDED BY ADSORPTIVE COLLECTION OF CYCLOHEXANE-1,2-DIONE DIOXIME COMPLEXES.** A highly sensitive voltammetric technique was developed for the direct determination of cobalt and nickel in seawater at picomolar and nanomolar concentrations, respectively. Detailed experiments were conducted to determine the optimal ligand type and concentration, buffer type and concentration, pH, and desorption potential. Replicate analyses of seawater reference materials yielded excellent agreement with certified values. Analytical precision for Co and Ni at coastal and open ocean concentrations was approximately  $\pm 5\%$  relative standard deviation. (Edited author abstract) 20 refs.

Donat, John R. (Univ of California, Santa Cruz, CA, USA); Bruland, Kenneth W. *Anal Chem* v 60 n 3 Feb 1988 p 240-244.

**093283 DETERMINATION OF TRACE METALS IN SEAWATER BY GRAPHITE FURNACE ATOMIC ABSORPTION SPECTROMETRY AFTER PRECONCENTRATION USING SYNERGISTIC EXTRACTION.** Trace Cd, Mn, Pb, Co, Ni, and Cu have been quantitatively separated and concentrated from seawater matrices with a low concentration (mmol dm<sup>-3</sup> level) of 1,1,1-trifluoro-4-mercapto-4-(2-thienyl)-3-buten-2-one and triethylphosphine oxide cyclohexane solution. The synergistic extract was directly injected into the furnace and a reproducible signal with little memory effect was obtained. The extracted adduct enhanced the AAS sensitivity during thermal decomposition processes, and simultaneously resulted in depression of the interferences. The detection limits of the analytes ranged from several ng dm<sup>-3</sup> to 100 ng dm<sup>-3</sup>. The proposed technique provides both the preconcentration and determination for trace analysis by a single extraction using a small volume of sample. Coastal seawater samples were analyzed by the method. (Author abstract). 16 refs.

## SEAWEED

## Analysis

**093284 ACCUMULATION DES METAUX LOURDS PAR CYSTOSEIRA BARBATA FORMA REPENS. APPLICATIONS BIOTECHNOLOGIQUES.** [Accumulation of Heavy Metals by *Cystoseira Barbata Forma Repens*: Biotechnological Applications]. The ability of *Cystoseira barbata* f. *Repens*, a brown seaweed, to accumulate heavy metals was studied for possible applications in marine or lagoon decontamination. Weed was sampled in its natural environment and cultivated in filtered seawater containing Cd, Cu, Pb or Zn. The effects of the kind of metal and of concentration on growth and morphogenesis were studied. The effect on these two features varied from one pollutant to another. However, *C. barbata* f. *repens* took up heavy metals in all cases with fairly high concentration factors: approximately 1300 for copper, 300 to 400 for the other metals. Concentrations of Cu, Cd, Pb and Zn in the weed reached 50, 1, 5.6 and 50 mg g<sup>-1</sup> dry weight respectively. This species could therefore be used for the decontamination of certain marine environments. (Author abstract) In French. 22 refs.

## Drying

**093285 PRESERVATION OF SARGASSUM TENNERIMUM J. AG. WITH FORMALIN AND OPEN-AIR DRYING AND ITS EFFECT ON QUALITY AND QUANTITY OF ALGINATE.** Sargassum *Tennerimum* J. Ag. can be effectively preserved by pretreatment with formalin followed by open-air drying on ground or horizontally suspended ropes. More than 90 percent of moisture can be removed within 20 to 36 hr on rope while on grid it requires 52 to 108 hr and on ground more than 100 to 108 hr. The plants treated with 2% formalin and dried at 23 cm thick beds on ground or at 5 kg.m<sup>-1</sup> beds on rope had high concentration of extractable alginic acid. Significant increase in viscosity was observed when *S. tenerimum* was treated with 5% formalin and dried on rope or ground. However drying on grid, even after pretreatment with formalin, tremendously reduced the viscosity of alginate. Plants treated with 5% formalin for 1 hr and dried at 23 cm thick beds on ground showed the highest viscosity. (Edited author abstract) 25 refs.

**093288 NO LOCK, SAFE OR BURGLAR ALARM CAN STOP A THIEF WITH A KEY.** Last year, bank employees stole nine times more money than bank robbers. That's not unusual. It happens every year in every industry. Employee theft cost US business over \$1 billion in 1984. The only way you can stop the rise in employee theft is to stop hiring applicants who pose a risk. You can do that by developing a stringent pre-employment screening process. (Author abstract) 5 refs.

O'Kelly, June P. (Equifax Services Inc, Atlanta, GA, USA). *Nucl Mater Manage* v 16 1987, INMM 28th Annu Meet: 'Safeguards - A Mature Technol?', Newport Beach, CA, USA, Jul 12-15 1987 p 181-184.

**093289 WATCH - A LOW-COST, SECURE-ITEM MONITORING SYSTEM.** Sandia National Laboratories has developed a remote sensor package that provides a low-cost, convenient way of monitoring item movement. Originally, the package was intended for use in valve monitoring, but it is now possible to use it in any sensor application where hardware installation is impractical or uneconomical. Full system implementation includes a receiver/controller which correlates the arrival time of RF signals generated by item-monitoring transmitters to increase communication security. Wireless Alarm Transmission of Container Handling (WATCH) is such a system. One important application of WATCH is in storage vaults where there are a number of material containers. Applying WATCH to inventory control reduces inventory workload and employee exposure rates; the system also provides quick access to inventory information by interfacing the system with plant site computer systems. (Author abstract)

Sanderson, S.N. (Sandia Natl Lab, Albuquerque, NM, USA). *Nucl Mater Manage* v 16 1987, INMM 28th Annu Meet: 'Safeguards - A Mature Technol?', Newport Beach, CA, USA, Jul 12-15 1987 p 310-315.

**093290 INTELLIGENT CARD ACCESS KEYS.** A newly developed access control technology allows information about users to be stored on key-like EEPROM devices. The keys store encrypted information about the user and his or her authorized access activity. Specially developed key readers scan, decrypt, and process the key data, and make the decision whether entry should be granted or denied. The key readers can function as complete, stand-alone facility management systems, incorporating access control security monitoring, and remote control. Key readers can also be interconnected with an MCM-1000 Multiplex Monitoring System to form a distributed processing local area network. (Edited author abstract)

Tennefoss, Michael R. *Nucl Mater Manage* v 16 1987, INMM 28th Annu Meet: 'Safeguards - A Mature Technol?', Newport Beach, CA, USA, Jul 12-15 1987 p 430-437.

**093291 ELECTRONICALLY ENHANCED SECURITY SYSTEM USING PLASTIC SCINTILLATORS FOR SPECIAL NUCLEAR MATERIAL DETECTION.** The Electronically Enhanced Security System at the Department of Energy Rocky Flats Plant (RFP), operated by Rockwell International, in Golden, Colorado, includes a Special Nuclear Material (SNM) monitoring system. The Enhanced Security System has numerous areas or posts that are each monitored by the following equipment for alarm detection: plastic scintillators, solid-state color cameras, microwave occupancy detectors, and audio and visual alarmed condition indicators. At centralized guard posts, assessment of an alarm is accomplished by using time-lapse color video cassette recorders, alarm annunciators, an intercom system, dedicated color monitors, and an alarm color monitor. As a pilot program, the Enhanced Security System accomplished a considerable yearly cost savings. (Edited author abstract) 2 refs.

**093293 DEVELOPMENT OF REAL TIME ALARM/SURVEILLANCE SYSTEM.** PNC has carried out real time alarm/surveillance system as part of its R&D programs on the physical protection systems for its nuclear facilities from 1984 to 1986. The guard operates a closed circuit television (CCTV) camera to see whether the alarms are caused by intruders or by accidents in the existing physical protection systems. But it is very difficult to assess rapidly moving objects using such a TV system. Monitor images are used to be continuously recorded by VTR, but this does not seem to be very suitable for it takes quite a long time to play back. Aiming at more effective and reliable physical protection systems, a new alarm/surveillance system was developed; the system detects persons entering into the surveillance zone and provides effective means to confirm. (Edited author abstract)

## Computer Aided Analysis

**093294 USE OF COMPUTER PROGRAMS TO EVALUATE EFFECTIVENESS OF SECURITY SYSTEMS.** Thirty or more computer programs for security vulnerability analysis were developed from 1975 through 1980. Most of these programs are intended for evaluating security system effectiveness against outsider threats, but at least six programs are primarily oriented to insider threats. Some strengths and weaknesses of these programs are described. Six of these programs, four for outsider threats and two for insider threats, have been revised and adapted for use with IBM personal computers. (Edited author abstract) 29 refs.

## Design

**093296 SECURITY ENGINEERING.** Effective security design requires a detailed analysis of assets, threats, vulnerabilities, and protective measures. This analysis is called security engineering. The US, like most other nations, has much experience in security engineering for wartime; however, there is a great lack of experience in engineering against terrorist threats. A new Army guide entitled *The Security Engineering Manual* attempts to fill this void by expanding the scope of security engineering to include terrorist and other 'peacetime' threats. Security engineering design is a step-by-step process that requires team input. It begins at the initial facility planning stage and continues through final design. There are six steps in the process.

Trout, John E. (Corps of Engineers' Protective Design Cent, Omaha, NE, USA); Betts, Curt P. *Mil Eng* v 80 n 522 Jul 1988 p 368-371.

## Equipment

**093297 EVOLUTION OF INTERIOR INTRUSION DETECTION TECHNOLOGY AT SANDIA NATIONAL LABORATORIES.** Interior Intrusion Detection Technology began at Sandia National Laboratories (SNL) in 1975 as part of the Fixed Facilities Physical Protection Research and Development program sponsored by the US Department of Energy in connection with their nuclear safeguards effort. This paper describes the evolution of Interior Intrusion Detection Technology at Sandia National Laboratories from the beginning of the Interior Sensor Laboratory to the present. (Edited author abstract) 8 refs.

## Evaluation

**093298 USE OF INFORMATION RESOURCE MANAGEMENT (IRM) IN SUPPORT OF THE INSPECTION AND EVALUATION PROGRAM FOR DOE/OSE.** The Department of Energy, Office of Security Evaluations (DOE/OSE) is in the process of enhancing its inspection and evaluation programs in order to improve their effectiveness. The overall goal is to enhance the ability of OSE to make positive and gradual impacts on DOE's efforts to maintain and improve security at its nuclear facilities. This goal will be met by developing inspection and evaluation procedures that provide thorough, realistic, and unbiased judgements during inspections; produce reliable and rational inspection and evaluation results; are acceptable throughout DOE; and are defensible to criticism. These inspection and evaluation procedures will eventually result in inspections that will more realistically stress the safeguards and physical security at a site based on the accepted standards for that site. (Edited author abstract)

**Imaging Techniques** See Also IMAGE PROCESSING; IMAGE PROCESSING—Reconstruction; PATTERN RECOGNITION SYSTEMS.

**093299 IMAGE-BASED SURVEILLANCE AND SECURITY SYSTEMS USING PERSONAL COMPUTERS FOR DEVICE AIMING AND DIGITAL IMAGE COMPARISON.** Image-based security systems should not be considered a total replacement for security personnel. The use of data links for positioner control means that imagers can be placed in very remote locations. This may reduce manpower requirements because fewer field observers will be required. However, a basic staff capable of responding quickly to any design-parameter security threat must still be maintained. In a well designed system, imagers and computers should work in conjunction with required manpower, not as a separate entity. This will provide the earliest detection of potential security threats thereby affording maximum time for adequate response.

**Inspection** See Also DATA PROCESSING—Security of Data; INSPECTION; NUCLEAR POWER PLANTS—Safeguard Systems.

**093300 CONDUCTING AN INSPECTION OF PROTECTION PROGRAM OPERATIONS.** Protection Program Operations (PPO) encompasses the entire physical security program at a facility, including security construction and equipment, procedures, forces, management and supervision, and the integration of these elements into a total system. PPO subtopics are Physical Security Systems (PSS), Protection Forces (PF), and System Performance Tests (SPT). PSS assesses those security elements designed to protect security interests, and includes sensors, surveillance devices, systems for transmission and integration of alarm and assessment information, barriers, lighting, etc. PF assesses the management, training, equipment and facilities, and skills and knowledge of the protective force. SPT includes Force-on-Force, Emergency Management Performance Test, and Limited Scope Performance Tests. (Author abstract)

**093301 OSE INSPECTION OF PROTECTION PROGRAM OPERATIONS: FIELD PERSPECTIVE OF INSPECTIONS.** Protection Program Operation includes three functional areas: Physical Protection Systems, Protective Forces, and System Performance Testing. The Office of Security Evaluations (OSE) inspects field offices in these areas by evaluating programs relative to Standards and Criteria and by performing a variety of exercises and other types of tests to assure protective systems are effective and maintained at a proper level to meet the defined threat. Our perception of the OSE inspection has been positive. The approach taken by ID, with key areas/activities emphasized, during each phase of the field inspection process is described in this report. (Edited author abstract)

**093302 OSE INSPECTION OF COMPUTER SECURITY: REVIEW.** The inspection process within the Department of Energy (DOE) serves the function of analyzing and reporting on the performance of security measures and controls in specific areas at sites throughout DOE. Three aspects of this process are discussed based on experience in computer security: Policy basis of performance inspections; Role and form of standards and

criteria in inspections; and Conducting an inspection using the standards and criteria. (Edited author abstract)

## Personnel Training

**093303 SECURITY PERSONNEL TRAINING USING A COMPUTER-BASED GAME.** Security personnel training is an integral part of a total physical security program, and is essential in enabling security personnel to perform their function effectively. Several training tools are currently available for use by security supervisors, including: textbook study, classroom instruction, and live simulations. However, due to shortcomings inherent in each of these tools, a need exists for the development of low-cost alternative training methods. This paper discusses one such alternative: a computer-based, game-type security training system. This system would be based on a personal computer with high-resolution graphics. Key features of this system include: a high degree of realism; flexibility in use and maintenance; high trainee motivation; and low cost. (Author abstract) 4 refs.

Ralph, J. (Booz, Allen & Hamilton Inc, Seabrook, MD, USA); Bickner, L. *Nucl Mater Manage* v 16 1987, INMM 28th Annu Meet: 'Safeguards - A Mature Technol?', Newport Beach, CA, USA, Jul 12-15 1987 p 71-76.

**093304 PRELIMINARY DESIGN FOR AN INSTITUTIONAL NEEDS ASSESSMENT PROCESS TO GUIDE THE DEVELOPMENT OF TRAINING PROGRAMS AT THE DEPARTMENT OF ENERGY CENTRAL TRAINING ACADEMY.** In order to provide and maintain a high level of nuclear security at DOE installations, the Office of Safeguards and Security (OSS) is charged with the deployment of highly trained security staff at each DOE site. Faced with this mission, OSS must ensure that both Safeguards and Security personnel are adequately trained to meet present as well as potential future insider and outside threats. A major step toward meeting this goal was to begin to standardize training, and create a central training facility to implement training for safeguards and security personnel. (Edited author abstract) 2 refs.

## Planning

**093305 MASTER PLANNING FOR SUCCESSFUL SAFEGUARD/SECURITY SYSTEMS ENGINEERING.** The development and phased implementation of an overall master plan for weapons systems and facilities engaged in the complexities of high technology provides a logical road map for system accomplishment. An essential factor in such a comprehensive plan is development of an integrated systems security engineering plan. Some DOD programs use new military regulations and policy directives to mandate consideration of the safeguard/security disciplines be considered for weapons systems and facilities during the entire life cycle of the program. The emphasis is to make certain the weapon system and applicable facilities have complementary security features. Together they must meet the needs of the operational mission and, at the same time, provide the security forces practical solutions to their requirements. This paper discusses the process of meshing the safe-guards/security requirements with an overall master plan and the challenges attendant to this activity. (Author abstract)

que, NM, USA). *Nucl Mater Manage* v 16 1987, INMM 28th Annu Meet: 'Safeguards - A Mature Technol?', Newport Beach, CA, USA, Jul 12-15 1987 p 65-67.

**093306 VULNERABILITY ASSESSMENT: DETERMINING PROBABILITIES OF NEUTRALIZATION OF ADVERSARIES.** The Security Manager charged with the responsibility of designing Safeguards and Security Systems at Department of Energy facilities must take many factors into consideration. There must be a clear understanding, supported by documented guidance, of the level of threat to be addressed, the nature of the facility to be protected, and the funds available to design, implement, and maintain the Safeguards and Security System. In order to successfully assess the security system the security manager must have in depth working knowledge of all facility and security system characteristics, and how the characteristics impact on the ability to defeat adversaries. Each tactic of a potential adversary strategy must be considered, and each tactic of the security forces strategies must be measured against the adversary tactics and strategy.

## Research

**093307 LABORATORY TOOL FOR THE DEVELOPMENT OF INTRUSION DETECTION SYSTEMS.** Learning systems present an attractive solution to the intrusion detection problem in situations where scenarios change, and where false alarms are costly. General Research Corporation (GRC) has developed a system for perimeter intrusion detection, and in comparison tests demonstrated false alarm reductions from 2.4 to 8.5 over single-sensor fixed processing systems. From this work, the concept of the Prototyping System has evolved. The Prototyping System is a laboratory tool for rapid and inexpensive layout of sensors and processing for physical security systems. Waveshapes can be measured and then tested for capability of discrimination between nuisances and intruders. The system facilitates performance comparisons between individual sensors and sensor groups, and rapid optimization of processing parameters. (Author abstract) 6 refs.

**093308 R&D/OPERATIONAL MC&A INTER-FACE.** Improvements in our ability to do materials control and accounting (MC&A) have been steady since the beginning of the nuclear age and the appearance of processes and facilities for handling nuclear materials. The motivation for these improvements has not been just safeguards: the desire for better process control also has played a major role, and the emergence of technology focused on the problems of MC&A has made it possible to pursue such improvements. However, it is a continuing challenge to match the needs of the operational MC&A elements with the capabilities and resources of the R&D community. (Edited author abstract) 5 refs.

## Sensors

**093309 MOVEMENT DETECTION.** This paper considers the three major detection technologies currently employed in intruder detection: passive infra-red; ultrasonic; microwave. The theory and application of each technology is discussed separately. The benefits of advanced and dual technology sensors are outlined. Selection criteria are proposed based on risk assessment and environmental suitability. (Author abstract)

**093310 DEVELOPMENT AND SIGNIFICANCE OF THE DOE SAFEGUARDS AND SECURITY STANDARDS AND CRITERIA.** In October 1985, the DOE Assistant Secretary for Defense Programs created a task force to develop inspection standards and criteria for Safeguards and Security. These standards and criteria (S/C) would provide the DOE Inspection and Evaluation (I&E) teams with the guidance needed to assess the security posture of DOE's nuclear and other important facilities. This paper discusses the process used to achieve the desired end result and the significance of the Task Force's accomplishments. (Edited author abstract)

**093311 WHAT ARE THE ATTRIBUTES OF A GOOD STANDARD AND ASSOCIATED CRITERIA?** The Department of Energy (DOE) Standards and Criteria (S&C) provide the framework upon which Office of Security Evaluations (OSE) inspections of safeguards and security at DOE facilities are conducted. The S&C were created to assure that inspections are comprehensive, standardized to the extent possible and accurately reported in meaningful terms, and that assessments are objective. With these goals in mind, the desirable attributes of a standard and its associated criteria are relevance, inspectability, and limited need for inspector judgement. (Author abstract)

**093313 LOGISTICAL AND SAFEGUARDS ASPECTS RELATED TO THE INTRODUCTION AND IMPLEMENTATION OF VIDEO SURVEILLANCE EQUIPMENT BY EURATOM.** With the growing availability of reliable video equipment for surveillance applications in safeguards and the disappearance of the Super 8 mm cameras, there will be a period of transition from film camera to video surveillance, a process which started two years ago. This gradual transition, as the film cameras come to the end of their useful lives, will afford the safeguards authorities the opportunity to examine in detail the logistical and procedural changes necessary. This paper examines, on the basis of existing video equipment in use or under development, the differences and problems to be encountered in the approach to surveillance. (Edited author abstract) 3 refs.

**093314 MODULAR INTEGRATED VIDEO SYSTEM (MIVS).** The Modular Integrated Video System (MIVS) is being developed for the International Atomic Energy Agency (IAEA) for use in facilities where mains power is available and the separation of the Camera and Recording Control Unit is desirable. The system is being developed under the US Program for Technical Assistance to the IAEA Safeguards (POTAS). The MIVS is designed to be a user-friendly system, allowing operation with minimal effort and training. The system software, through the use of a Liquid Crystal Display (LCD) and four soft keys, leads the inspector through the setup procedures to accomplish the intended surveillance or maintenance task. Review of surveillance data is accomplished with the use of a Portable Review Station. This Review Station will aid the inspector in the review process and determine the number of missed video scenes during a surveillance period. (Author abstract)

**093315 VIDEO AUTHENTICATION TECHNIQUE.** Unattended video surveillance systems are particularly vulnerable to the substitution of false video images into the cable that connects the camera to the video recorder. New technology has made it practical to insert a solid state video memory into the video cable, freeze a video image from the camera, and hold this image as long as desired. Various techniques, such as line supervision and sync detection, have been used to detect video cable tampering. The video authentication technique described in this paper uses the actual video image from the camera as the basis for detecting any image substitution made during the transmission of the video image to the recorder. The technique, designed for unattended video systems, can be used for any video transmission system where a two-way digital data link can be established. (Edited author abstract)

**093316 VIDEO IMAGING SYSTEM FOR DETECTION, TRACKING, AND ASSESSMENT (VISDTA).** Automatic scene scanning and digital video processing are combined in a sensor/assessment system called VISDTA. In fixed-site or mobile security applications, the operator can initiate automatic scene scanning. While scanning, detection algorithms process video from a thermal imager or low-light camera. An additional detection algorithm operates on single fixed scenes. Video is displayed with graphics on a monitor next to the operator's touch-panel display. Assessment by the operator is aided by zoom/-focus control, pan/tilt control, and range measurements. Detection ranges can be kilometers. In this paper, the system design is described, along with highlights of the user interface, and performance estimates are made. (Author abstract)

**093317 EFFECT OF SEDIMENTATION FEED FLUX ON THE SOLIDS FLUX CURVES.** The solids flux curve was determined using an experimental procedure based on measuring the concentration at various heights of a bed of settled solids formed during a semicontinuous sedimentation test. The flux curve was found to be dependent on the system feed flux. This dependence is due to inertial forces near the surface of the bed which should depend on the feed flux. At a given feed flux, there was good agreement between the solids flux curve determined by the new method and continuous sedimentation results. (Edited author abstract) 7 refs.

**093318 COLLISION EFFICIENCY AND COLLOIDAL STABILITY OF UNEQUAL SIZE SPHERICAL PARTICLES MOVING THROUGH QUIESCENT VISCOUS LIQUID.** Collision efficiencies have been computed for unequal-size spherical particles settling in quiescent viscous liquids, taking into account the hydrodynamic interaction, interparticle attraction and electrostatic repulsion. The results are closely related to the mechanism of coagulation of colloidal particles in a sedimentation field. If the interparticle attraction and electrostatic repulsion are both negligibly small as compared to viscous drag, the collision efficiency  $\eta$  is very small, i.e. about 0.003. However, a relatively large Van der Waals force makes  $\eta$  greater than unity. As the ratio of the radii of the two particles (smaller divided by larger) decreases the collision efficiency also decreases. (Edited author abstract) 13 refs.

**093319 CASCADE-SIEVE SHAKER FOR RAPID PARTICLE SIZE ANALYSIS OF COARSE SEDIMENT.** A new sieving apparatus and an analytical method have been developed and used for rapidly defining the particle-size distribution of sediment coarser than 0 millimeter. The apparatus consists of inner and outer support frames, a series of rectangular sieve screens that are arranged in an alternating cascade fashion, and a mechanism for vibrating the inner frame and screens vertically at a frequency of 3.7 Hertz. Sediment introduced on the topmost sieve is vibrated through the system. Particles that pass through a sieve are directed to the next finer sieve, whereas particles that are retained are shunted off into a collection container. Size separates in the collection containers are weighed cumulatively on an electronic balance, and the particle-size distribution is calculated automatically by computer. (Edited author abstract) 3 refs.

## Classification

**093321 BASAL MIXING ZONES IN LOESSES OF LOUISIANA AND IDAHO: I. IDENTIFICATION AND CHARACTERIZATION.** The thickness and character of basal mixing zones in loess with different underlying materials and in different climates were studied in Louisiana and Idaho. Peoria loess in Louisiana is underlain by sandy braided stream deposits, clayey alluvium, and an older Sicily Island loess. In Idaho, materials underlying loess deposits include glacial till, basalt, Pliocene sediments, and a paleosol developed in loess. Multiple criteria, divided into primary and secondary indicators, were used in the identification of basal mixing zones. The primary indicators of basal mixing zones were field morphology and particle-size distribution. Secondary indicators include total elemental analyses, clay mineralogy,  $\text{CaCO}_3$  equivalence, exchangeable cations and soil reaction listed in order of decreasing sensitivity. (Edited author abstract) 23 refs.

## Computer Applications

**093322 SEDIAT: A BASIC PROGRAM FOR THE COLLECTION AND STATISTICAL ANALYSIS OF PARTICLE SETTLING VELOCITY DATA.** SEDIAT is a series of compiled IBM-BASIC (version 2.0) programs that direct the collection, statistical calculation, and graphic presentation of particle settling velocity and equivalent spherical diameter for samples analyzed using the settling tube technique. The programs follow a menu-driven format that is understood easily by students and scientists with little previous computer experience. Settling velocity is measured directly (cm/sec) and also converted into Chi units. Equivalent spherical diameter (reported in Phi units) is calculated using a modified Gibbs equation for different particle densities. Input parameters, such as water temperature, settling distance, particle density, run time, and Phi/Chi interval are changed easily at operator discretion. Optional output to a dot-matrix printer includes a summary of moment and graphic statistical parameters, a tabulation of individual and cumulative weight percents, a listing of major distribution modes, and cumulative and histogram plots of a raw time, settling velocity, Chi and Phi data. (Author abstract) 15 refs.

**093323 COMPUTER PROGRAMME FOR CALCULATING FREE SETTLING TERMINAL VELOCITIES.** The underlying principles and the algorithm for developing a computer programme for estimation of free settling terminal velocities of particles have been discussed. The programme, written in BASIC language, selects the appropriate equation for estimation of terminal velocity depending on a particular combination of properties of particles (size and density) and the medium of suspension (density and viscosity). Possible modifications of the programme to suit a variety of conditions are also discussed. (Edited author abstract) 7 refs.

## Computer Simulation

**093324 DEPOSIM: A MACINTOSH COMPUTER MODEL FOR TWO-DIMENSIONAL SIMULATION OF TRANSPORT, DEPOSITION, EROSION, AND COMPACTION OF CLASTIC SEDIMENTS.** DEPOSIM is a dynamic deterministic two-dimensional simulation model implemented on an Apple Macintosh 512 kbyte computer that represents the interaction between transport, deposition, erosion, and compaction of clastic sediments. Sediment particles, transported within a fluid medium, are represented in a cross section through a sedimentary basin. The cross section is separated into discrete columns. The behavior of particles depends on velocity of the fluid in each column of the cross section, as well as on the basin's configuration, particularly on the steepness of slope of the seafloor. Fluid velocity depends on the velocity of the fluid newly supplied to the basin in each time increment, and on the depth of water in each column. Input parameters were taken from actual sedimentological and oceanographic literature that is concerned with clastic sediments. DEPOSIM takes into account up to three different particle sizes. Graphics subroutines display the cross sections and frequency distributions of particle sizes on a column-by-column basis.

## Electric Field Effects

**093326 ELECTROFORCED SEDIMENTATION OF THICK SLURRIES IN CONSOLIDATION REGION.** It is shown that the settling rates of thickened slurries can be greatly enhanced by application of D.C. voltages. It is demonstrated that the settling rates increase remarkably with increasing electric field intensity. The basic differential equation for gravitational settling of thick slurries is derived and this is extended to electroforced sedimentation. The theoretical settling rates and the porosity distributions in settling sediments of both gravitational and electroforced settling compare favorably with experimental observations. In addition, it is shown that the compression-permeability characteristics in the low compressive pressure region can be closely determined analytically by using batch sedimentation data. (Author abstract) 11 refs.

## Equipment

**093327 LAMELLA SETTLERS: MATERIAL BALANCES AND CLARIFICATION RATES.** We show

that material balances and clarification rates of a lamella settler can be obtained from the particle size distribution and density of the solid, the density and viscosity of the liquid, the desired concentration of solids in the overhead product, and the concentration of solids in the feed and underflow, using an algorithm based on a simple geometric model. The method was validated using concentrated suspensions (up to 20 vol% solids) of four different feed-particle size distributions of hydrargillite (aluminum hydroxide) in water. Most of the data were obtained in a 60-cm-long settler with 1-cm plate separation inclined at 60° to the horizontal in 'open bottom' and 'normal' configurations. The algorithm is not applicable to tube settlers, whose hydrodynamics are more complex. (Author abstract) 16 refs.

**Lead Determination** See GAMMA RAYS—Absorption.

**Mathematical Models** See Also RESERVOIRS—Management.

**093328 COMPRESSION ZONE EFFECT IN BATCH SEDIMENTATION.** Theories of batch sedimentation, taking into account the compression zone effect, are reinterpreted and modified. According to the discussion presented and the experimental results shown, characteristics - which are the loci of points representative of layers with the same settling rate and the same solids concentration in the settling zone - rise tangentially to the sediment curve on a height vs. time plot. Mathematical expressions that relate the solids concentration to the variations of the pulp-supernatant interface height and of the sediment height are presented. In addition, the model presented is proposed for use when it is not possible to measure the sediment height. A procedure for calculating the concentration at the top of the sediment is also indicated. Calcium carbonate suspensions in water were selected for testing the equations deduced. The relation between the continuous thickener unit area and the underflow solids concentration was obtained from the batch tests, and is compared with that calculated by the graphic methods. (Edited author abstract) 14 refs.

## Measurements

**093329 INFLUENCE OF THE CONCENTRATION OF THE DISPERSE PHASE (OCHER) ON THE FLOCCULATING ACTION OF HYDROLYZED POLYACRYLAMIDE.** The authors estimate the influence of the concentration of particles of the disperse phase on the sedimentation rate, as this is one of the most important characteristics of sedimentation processes in real systems. Experimental results show that the accelerated sedimentation of ochre due to addition of HPAA is especially pronounced in the region of low  $C_d$ ; the effect is strongest at  $C_d = 5 \cdot 10^{-4}$  mass %, and it weakens with increase of  $C_d$ . It is shown that the initial clarification rates (and therefore the rates of sedimentation of the ochre particles) depend strongly on  $C_d$ , and they cannot be used for strict quantitative assessment of the flocculating action of the polymeric flocculant. 10 refs.

Nagel', M.A. (S.M. Kirov Kazan' Inst of Chemical Technology, USSR); Valiulina, F.I.; Kurenkov, V.F.; Myagchenkov, V.A. *J Appl Chem USSR* v 60 n 1 pt 2 Jan 1987 p 145-148.

**093330 INFLUENCE OF SEDIMENTOMETER PARAMETERS ON ACCURACY OF ANALYZING SEDIMENT COMPOSITION.** Sources of errors in determining hydraulic grain size by sedimentometers are investigated. A differential equation of motion of the balance pan of the instrument is proposed. By solving this equation we calculate the measurement error caused by

oscillations of the balance pan. By comparing measurement results with standards we show the influence of the method of sample introduction on the accuracy of sedimentometric analysis. Recommendations are made for sedimentometer design. (Author abstract) 13 refs.

**093331 DEGREE AND STABILITY OF MAGNETIC DISPERSIONS: SEDIMENTATION, RHEOLOGICAL, AND MAGNETIC PROPERTIES.** There is a distinct correlation between the dispersion qualities of magnetic acicular particles as measured by slush grind rheology, sedimentation test, and coating magnetic properties. Sedimentation time measurement is a very sensitive tool to evaluate the degree of dispersion and dispersion stability. Sedimentation, rheology, and coating magnetic properties show that 'steric stability' is essential to maintain the excellence of magnetic particle dispersion. Some surface active agents provide excellent pigment dispersion but poor stability with time, whereas other chemical compounds adsorbed on a particle surface can provide a very high degree of dispersion with excellent dispersion stability. Results of particle size evaluation from sedimentation measurements show five to six times improvement in the degree of dispersion due to suitable surface active agents. (Author abstract) 10 refs.

## Sampling

**093332 SAMPLING TECHNIQUES FOR GRAVEL SIZED SEDIMENTS.** The methods commonly used for sampling the coarser surface layers of gravel-bed streams are reviewed. It is found that while an areal sample is biased toward the coarser grains compared with a volumetric sample of the same material, the conversion formula suggested by a voidless cube model overcompensates for this effect. A modified version of the cube model that accounts for porosity is proposed. The modified cube model and tests conducted with a real sampling using wax indicate that area-by-weight analyses can be converted successfully to the equivalent bulk sieve analyses. The average depth of the wax samples ranged from  $D_{65-91}$ , increasing with median grain size. The equivalence of the grid by number and bulk sieve analyses is reaffirmed. ## Structure

**093333 BASAL MIXING ZONES IN LOESSES OF LOUISIANA AND IDAHO: II. FORMATION, SPATIAL DISTRIBUTION, AND STRATIGRAPHIC IMPLICATIONS.** Basal mixing zones of loess with different underlying materials in Louisiana and Idaho have been identified. Formation of basal mixed zones occurs when loess is deposited on a pedogenically active surface and becomes incorporated into the underlying stratigraphic unit through bioturbation and pedoturbation processes. Factors influencing basal mixed zone formation include climate, nature of stratigraphic materials underlying the loess deposits, and rate of loess deposition. The warm, humid climate in Louisiana is more conducive to the formation of thicker basal mixed zones than the cool, semiarid climate of Idaho. In Louisiana, thicker basal mixing zones were found where loess was underlain by coarse textured, unconsolidated materials than where underlain by unconsolidated materials with similar or finer textures. (Edited author abstract) 21 refs.

## Suspensions

**093334 SEDIMENT DESORPTION OF PCB CONGENERS AND THEIR BIO-UPTAKE BY DIP-TERAN LARVAE.** Sediment desorption of PCB congeners and their bio-uptake by Chironomus tentans Fabricus were investigated in a continuous flow system. The desorption of 71 congeners (in Aroclors 1221, 1016, 1254 and 1260) determined by glass capillary gas chromatography could be described by a first order function. The release rate of the individual congeners was inversely related to their octanol/water partition coefficients ( $K_{ow}$ ). The depth of mobilization generally decreased with the number of chlorine substitutions and was inversely related to  $K_{ow}$ . Bio-uptake of the congeners by Chironomus tentans Fabricus was selective with the bio-uptake factor being highest for those with 2-4 chlorines. There was no correlation between the factor and either  $K_{ow}$  or desorption rate from the sediments. (Author abstract) 38 refs.

**093335 WAVE-INDUCED INSTABILITY IN SANDY SUBMARINE SEDIMENTS.** The influences of the effective stress change induced by harmonic ocean waves on the stability of sandy submarine sediments in very gently sloped seafloors are examined. The general solution of the problem of flow through poro-elastic media and their deformation is represented by a linear combination of the solution of the Laplace equation and the diffusion equation (consolidation equation). The solution for horizontal seafloors is assumed to be approximately applicable to a very gently sloped planar seafloor. All possible arc failures are found by trial, using the slice method. The geometry of the possible instability is represented by the envelope of all the possible slides. The effective stress changes under the troughs towards the still water level of the storm waves in the direction of wave propagation can cause circular arc failures in sediments with Skempton's pore pressure coefficient,  $B$ , of less than 0.8, in water depths down to about 100m. The length of the largest failure arc is of the order of 1/9 approx. 2/9 of the wavelength, and the length of the composite failure zone can be about 3/4 of the half wavelength. The depths of the slip circle penetration can be of the order of the wave amplitude. (Author abstract) 12 refs.

**093336 SPATIALLY DISTRIBUTED RECEPTION OF SEISMIC WAVES.** The possibility of implementing, a selective (as regards the direction and distance) reception of seismic waves by recording the amplitudes of the natural forms of a body immersed in the ground, is considered. It is shown that, with the growth in the number of the observed shapes, the signal-to-noise ratio on the reception side can attain the same level as at the radiation point. Methods of recording the amplitudes of natural forms, and the errors connected with the finality of the number of the observed forms are discussed. (Translated author abstract) 2 refs. In Russian.

**093338 ZASTOSOWANIE TEORII SPLINE OW DO WYZNACZANIA POL PREDKOSCI FAL SEJS-MICZNYCH.** [Application of the Spline Theory to the Determination of the Velocity Field of Seismic Waves]. An algorithm was constructed for the determination of the velocity field of seismic waves on the basis of their measured travel times. This general approximation problem has been solved with the aid of the spline functions technique. Such an approach enables a continuous velocity field to be obtained. An algorithm in this form can be used to investigate the seismic velocity field with only limited alterations such as, for example, in a confined rock massif including a coal mine. **093339 VZTAH SEISMICKEHO NEKLIDU U STRUKTURY PROSTREDI.** [Interrelationship between Seismic Noise and Structure of the Environment]. The paper is devoted to the seismic noise in the frequency band approx. several Hz to several tens of Hz. The noise is assumed to be created mainly by surface waves. Assuming a regular distribution of the noise sources along Earth's surface, the ratios of the seismic noise amplitude spectra in known structures were estimated using the matrix method. The estimated spectral ratios principally differed from the measured ones. The discrepancy between estimates and measurements seems to be caused at least by an irregular distribution of the noise sources, which strongly influence the spectral ratios. Moreover, the seismic noise sources in the frequency band considered appeared to be nonstationary. (Edited author abstract) In Czech. 6 refs.

**093340 WAVES CAUSED BY MOVING LOADS IN AN ISOTROPIC LAYER INHOMOGENEOUS THROUGH THE THICKNESS.** Problems on motion with a constant subseismic velocity of an oscillating load on the boundary of an isotropic elastic layer inhomogeneous over the thickness are studied in a three-dimensional formulation. Quantitative estimates are given for the upper limits on the magnitudes of the velocity of motion and the load vibration frequency for which a unique solution exists for the problem in energy classes. In cases

when no energy solution exists, principles are formulated to extract the unique solution and a solution is given in the far field. Results are presented of numerical computations of the waves field characteristics in the cases of the motion of a normal concentrated load in a homogeneous layer. Situations are noted in which a different number of waves propagates in different layer domains. The problems considered are of interest for seismology and in designing aerodrome coverings. **093341 FAULT LENGTH OF SMALL-SIZED EARTHQUAKES AS ESTIMATED FROM THE PULSE WIDTH OF INITIAL P WAVE.** The pulse width of the initial P wave was measured for about 300 aftershocks of the western Nagano, Japan earthquake of September 14, 1984. Based on the data set, the statistical relationship between the fault length L (km) and earthquake magnitude determined by the Japan Meteorological Agency  $M_j$ ,  $\log L = 0.58 M_j - a$  was established for the magnitude range of  $M_j = 3-5$ . The constant a takes the value of 2.48-2.64 depending on the fault type assumed. It appears that this formula may give a good estimate of the fault length even for larger earthquakes of  $M_j$  up to 8. The L- $M_j$  relation is converted to  $M_0 = b \times 10^{2.2 L^{2.3}}$  where  $M_0$  is the seismic moment (dyn-cm), and b is a constant taking the value of 4.9-11.4 corresponding to a. This relation predicts that the stress drop associated with fault rupture increases with the seismic moment of an earthquake. (Author abstract) 18 refs.

**093342 NUMERICAL STUDY OF CAUSTICS AND POLARIZATIONS OF SEISMIC WAVES INTERACTING WITH THE THREE-DIMENSIONAL GEOLOGICAL STRUCTURES.** Ray tracing in three-dimensional, piecewise continuous models of near-surface geological structures is used to study the geometry of caustics and wave polarizations induced by refracted and multiply reflected high frequency seismic waves. The geological structures modeled are sediment-filled basins and curved reflectors. We show that multiply reflected seismic P-waves may easily induce localized intensification of both vertical and horizontal motions at the ground's surface. The results may be of importance to the prediction of earthquake hazards in urban areas. Additionally, we suggest applications to the study of the excitation of free oscillations of sedimentary and to the seismic detection of subsurface reflectors. (Author abstract) 10 refs.

**093343 LABORATORY MEASUREMENTS OF ELASTIC WAVE ATTENUATION BY SCATTERING DUE TO RANDOM HETEROGENEITIES.** Scattering attenuation and spatial fluctuation of P waves traveling through a scattering medium were examined experimentally by using an ultrasonic technique. 2-D models of random media used in laboratory experiments are characterized by a triangular correlation function and a 2.4 percent standard deviation in velocity and density. The range of wave length covered in the experiments corresponds to  $2 + LS/ka < 33$ , where k is the wave number and a is the correlation distance of the heterogeneities, i.e., the heterogeneity size. The results obtained lead to the conclusion that forward scattered energy should not be counted as lost energy when the scattering attenuation of seismic waves traveling through a scattering medium is

calculated. It is suggested that initial motions as well as the subsequent phase of direct P or S wavelets are strongly contaminated by nonuniform forward-scattered energy; Fourier amplitudes for entire parts of the wavelets should be used to determine the attenuation of the waves as a function of frequency. 29 refs.

## Computation

**093344 LINE SOURCES FOR SEISMIC MODELING BY FINITE DIFFERENCES IN INHOMOGENEOUS MEDIA.** Initial (source) conditions for second-order finite-difference seismic-wave equation computations are usually implemented by inserting an analytic solution of the wave equation into the finite difference grid at two successive time steps. This approach is difficult to use in an arbitrarily inhomogeneous model and when free-surface boundary conditions are a required component due to proximity of the source to that surface. These problems can be overcome by noting that a small aperture behaves as a point source. In this algorithm, an aperture placed at the free-surface admits energy to the inhomogeneous structure from a small portion (a 'line') of a wavefront propagating in an auxiliary homogeneous medium defined above the free-surface. ## Computer Simulation

**093345 LARGE-SCALE, EXPLICIT WAVE SIMULATIONS ON THE CRAY-2.** Most time-domain, wave modeling problems in geophysics are intractable by classical analysis methods, due principally to nonseparability and to a lesser extent material nonlinearity. Therefore discrete numerical solutions are often necessary for the simulation of realistic models. Applications in 2-D and 3-D geophysical modeling are the subject of this paper, particularly as solved on a CRAY-2 supercomputer. Implementation and performance differences between earlier CRAYs and CRAY-2 are described, including the discrepancy between scalar fetch and vector processing speeds. Explicit finite element solvers are applied to applications involving 2-D simulation of a seismic refraction experiment across the state of Maine, 3-D simulation of near-source scattering experiments, and both linear and nonlinear axisymmetric source simulation. Results show that the CRAY-2 allows cost-effective 2-D simulations of truly large-scale models, but only begins to be effective in 3-D for models of interest in geophysics. (Edited author abstract) 9 refs.

## Estimation

**093346 BAYESIAN ESTIMATION IN SEISMIC MIGRATION.** Seismic migration is a technique widely used in seismic oil exploration for wavefield reconstruction and for imaging the geometrical distribution of the reflection surfaces within the earth from the seismic data recorded on the earth surface. These data are usually corrupted by noise (white noise, surface waves, multiple reflections, etc.) that degrades the result of the migration. Another factor which influences the migration is the inadequate knowledge of the distribution of the acoustic-wave propagation velocity in the subsurface of the earth. The authors use estimation theory techniques to find the MAP (maximum a posteriori) estimate of the wave propagation velocity and of the geometrical distribution of the subsurface reflector points. 13 refs.

**093347 ONE-DIMENSIONAL SEISMIC INVERSION USING ADAPTIVE DECONVOLUTION.** This paper presents an adaptive deconvolution approach to one-dimensional normal incidence inversion of noisy seismic data. A layered system is considered, which is characterized by reflection coefficients and travel-times. The reflector model is assumed to be random, while the seismic source signature wavelet, which travels into the earth, is unknown and time-varying. A recursive instrumental variable algorithm is appropriately combined with a fixed-lag deconvolution and detection technique for adaptive estimation of the wavelet, reflection coefficients and travel-times. The proposed procedure includes a multiples suppression method, which is fed with the above estimates, constructs and removes from the given signal the part containing all significant multiple, transmission and absorption effects. Examples are given, which illustrate the derived results. (Author abstract) 16 refs.

**093348 ANALYSIS OF THE CHARACTERISTICS-INTEGRATION METHOD FOR ONE-DIMENSIONAL WAVE INVERSION.** Basing our work on the one-dimensional (1-D) wave equation, we present an inverse method which we call the characteristics-integration method. The method is derived from integration along characteristic families of straight lines of the wave equation in the time domain. With the source function known and reflection data recorded on the surface, the characteristics-integration method can efficiently and economically recover the subsurface impedance profile, provided that the structure is inhomogeneous only in the depth direction. **093350 PROPAGATION OF COMPLEX DISCONTINUITIES WITH PIECEWISE CONSTANT AND VARIABLE VELOCITIES ALONG CURVILINEAR AND BRANCHING TRAJECTORIES.** The method of functionally invariant solutions of wave equations utilizing the principle of superposition is used to construct exact solutions for a system of complex discontinuities propagating with piecewise constant velocities along curvilinear and branching trajectories. A passage to the limit is shown

in the course of which the solution constructed yields velocities along smooth curvilinear trajectories. It is shown that if the propagation of a major discontinuity (crack) begins with the formation of a pure shear element, then as the velocity increases, dislocation components of the displacement vector will appear at the discontinuity; if on the other hand the propagation of a major crack begins with the formation of a pure dislocation element, then as the velocity of propagation of the crack increases, it will branch and considerable shear components of the displacement vector will form on the branched segments of the crack. The minimum values of the branching angles are determined. Theoretical seismograms are given to illustrate the results. (Edited author abstract) 26 refs.

Bykovtsev, A.S. *Appl Math Mech* v 50 n 5 1986 p 620-628.

**093351 EFFECTS OF CANYON TOPOGRAPHY AND GEOLOGICAL CONDITIONS ON STRONG GROUND MOTION.** The finite and infinite element coupling system is used to study the effects of canyon topography and geological conditions on strong ground motion. The system is first applied to a semi-cylindrical shaped canyon using SH wave propagation to verify its accuracy. It is concluded that different topography conditions may have important effects on the ground motions along the canyon. The geological conditions, by which we mean different softening of weathered strata of the canyon surface, will have significantly amplified effects on the free field motions. This fact suggests that a deep weathered rock excavation of arch dam abutments for stability purposes will also benefit earthquake resistance of the dam due to the reduction of ground motions of the sound rock. (Author abstract) 11 refs.

**093352 ONE-DIMENSIONAL WAVE PROPAGATION IN A HIGHLY DISCONTINUOUS MEDIUM.** A pulse propagates through a one-dimensional medium consisting of a large number N of homogeneous layers. As it propagates the pulse, which consists of multiply scattered energy, is broadened and slightly delayed compared with the first arrival, which travels at the characteristic speed. R.F. O'Doherty and N.A. Anstey first studied this phenomenon in 1971 and gave an incomplete theory predicting the pulse shape and spectrum essentially by summing a diagram. We corroborate their results with a rigorous theory giving the limiting pulse shape as N approaches  $\infty$  while the reflection coefficients go to zero like  $1/\sqrt{N}$ . This work is novel in that: (a) a rigorous theory is given, (b) the development is in the time domain, and (c) probabilistic concepts, such as ensemble averages, are not used; spatial averages suffice. (Edited author abstract) 20 refs.

**093353 SOURCE WAVELET ESTIMATION BY UPWARD EXTRAPOLATION.** In this paper an extension of the theory of source wavelet estimation is proposed. As in previous publications, this method is based on extrapolation of the wave field measured at depth, upward to the free surface. The extrapolation is performed by using the finite difference approximation to the full inhomogeneous wave equation. The extrapolation results in a wavelet which generally includes ghosts and can be used for source signature deconvolution and deghosting. The method needs two closely spaced receivers and is applicable for arbitrary locations of the source and the receivers in one-dimensional multilayered models, provided the source is above the receivers; furthermore, it can be applied to both marine and land data. Application of the proposed method to a number of synthetic models shows that it gives a good estimate of the source wavelet. (Edited author abstract)

1988 p 158-166.

**093354 NEW ALGORITHM FOR FINITE-DIFFERENCE MIGRATION OF STEEP DIPS.** One-way wave propagation is formulated in the (x, t) domain as an integrodifferential equation and is applied to the migration of stacked data. A key step is to replace the phase-shift square root in the frequency-domain representation by an integral of a rational function; the resulting expression is interpreted in the space-time domain. Approximating the integral by a finite sum leads to a number of practical approximations, the lowest order being Claerbout's 15 degree equation and others being various high-order equations in the literature. Optimal mth-order quadrature formulas based upon Chebyshev criteria suggest a second-order approximation which takes 20 percent more time than the 15 degree equation but is accurate to over 50 degrees. **093355 THREE-DIMENSIONAL IMAGING OF STEEPLY DIPPING STRUCTURE NEAR THE SAN ANDREAS FAULT, PARKFIELD, CALIFORNIA.** Shot gathers from the Parkfield, California, deep crustal seismic reflection line, recorded in 1977 by COCORP, reveal coherent events having horizontal to reverse move-outs. These events were migrated using a multioffset three-dimensional Kirchhoff summation method. This method is a ray-equation back projection inversion of the acoustic wave field, which is valid under the Born, WKB, and far-field assumptions. Migration of full-wave acoustic synthetics, having the same limitations in geometric coverage as the COCORP survey, demonstrates the utility of the imaging process. The images obtained from back projection of the survey data suggest that the Gold Hill fault carries ultramafic rocks from the surface to 3 km depth at a dip greater than 45 degrees, where it joins the San Andreas fault. (Edited author abstract)

**093356 ROBUST DECONVOLUTION BY MODIFIED WIENER FILTERING.** To design a modified Wiener filter for deconvolution in the presence of additive noise, it is necessary to know the frequency characteristics of the wavelet precisely, plus the spectra of the input and additive noise. Typically, some appropriate estimate of the frequency function of the wavelet is taken, and the modified Wiener filter is designed from that estimate. A more realistic practical viewpoint is to think of the estimated wavelet response as one of a set of possible frequency response functions. By using statistical information obtained during wavelet estimation, a modified Wiener filter equivalent to a statistically robust deconvolution filter can be constructed. In this case 'robust' means that the error criterion which defines the deconvolution filter allows for the set of possible wavelet frequency functions. Two different error criteria are considered: (1) the minimization of the average mean-squared error, and (2) the minimization of the maximum mean-squared error. Deconvolution using an estimated wavelet can thus be made robust to wavelet uncertainties in an easily followed technique. (Edited author abstract)

**093357 SIMPLE APPROACH TO THE MASKED-LAYER PROBLEM IN SEISMIC REFRACTION WORK.** The effect of a masked layer (either due to velocity inversion or hidden layer condition) on seismic refraction interpretation is determined in a simple way using the delay-time concept and it is shown that the

error in the computed depth to the refractor below can be corrected easily, provided the velocity of the masked layer and its thickness or the thickness of the overlying layer are known. It is seen, extending the concept, that the depth to an interface obtained from the corresponding intercept time and average velocity of the multilayer overburden is always less than the true depth. Hence, large errors due to the presence of masked layers can be avoided by calculating depths using the average velocity or else the effective velocity estimated from the T-D graph, in refraction work. A multilayer field example is presented for illustration. (Author abstract) 5 refs.

**093358 REPORT 15. THE SEISMIC REFRACTION COMPRESSION-SHEAR WAVE VELOCITY RATIO AS AN INDICATOR OF SHALLOW WATER TABLES: A FIELD TEST.** To test the assumption that the velocity of shear waves increases much less than the velocity of compressional waves at a water table, a seismic refraction survey was performed over a shallow water table in alluvial sediment. Using a sledge hammer and a partially buried steel cylinder as a source, a maximum shot-to-receiver distance of 330 ft and depth of investigation of 60 ft were achieved. The ratio of  $V_p$  to  $V_s$  (compressional/shear wave velocity) at the water table was found to be 2.48. In the four nonsaturated layers above the water table,  $V_p/V_s$  ratios ranged from 1.54 to 1.55. As predicted by the theoretical models considered, shear wave velocity did not increase measurably at the water table. In an area in which a shallow water table was not likely to exist, shear wave velocity increased by at least as much as the increase in compressional velocity at each refractor. Results indicate that the comparison of S- and P-wave velocity profiles is a promising technique for water table detection. (Edited author abstract) 13 refs.

**093359 LABORATORY TESTS OF THE SINGLE- AND MULTIPLE-SCATTERING MODELS FOR THE GENERATION OF SEISMIC CODA WAVES.** To investigate the scattering property of the earth's crust using seismic coda waves, scattering models for coda generation were first tested using an ultrasonic technique and sufficiently large 2-D models of scattering media. Next, short-period coda waves from local small earthquakes that occurred in the central Kinki district of southwest Japan were analyzed with the multiple-scattering model for coda generation given by Gao et al. It was concluded that the multiple-scattering model of Gao et al. for coda generation explains the time decay of the amplitude of coda consisting of waves scattered by small-scale crack-like heterogeneities in the earth's crust very well. Also, when the lithosphere is assumed to be a scattering medium with randomly distributed heterogeneities, the isotropic scattering coefficient,  $g$ , of the earth's crust in the central Kinki district is nearly proportional to  $f^{1.0}$  in the frequency range of  $2 < f < 16$  Hz. It is suggested that the heterogeneities responsible for short-period coda generation may be numerous cracks in the crust that have lengths of less than about 100 m. 40 Refs.

**093360 WAVEFORM INVERSION USING SECONDARY OBSERVABLES.** A new method is proposed for inverting single-station surface-wave seismograms. Instead of inverting directly the time-signal, use is made of secondary observables built up from a set of time-frequency images. This allows us to enhance the sig-

nal-to-noise ratio and to make more linear the relationship between the model parameters and the inverted observables. The feasibility of the method is checked on multimode synthetics prior to present the inversion of a long-period multimode seismogram related to the Pacific Ocean. (Author abstract) 9 refs.

**093361 SEISMIC SPECTRA ON SOIL WITH UNCERTAIN PROPERTIES.** Expected spectral ordinates and their standard deviations are computed for ground motions produced by SH waves at the surface of a homogeneous soil formation resting on a half-space of rock. Wave transmission is idealized as linear and one-dimensional. Uncertainties about soil properties are taken into account using various approximations: a Taylor series expansion of the Fourier spectrum magnification factors with different numbers of terms and different intervals for numerical differentiation; discretization of the joint probability density function of the soil properties so as to match its moments up to those of third order including the crossed moments; a discretization that matches up to some fifth-order moments; and a fine numerical integration for the marginal density function of the modulus of rigidity, discretizing the rest of the density function. The latter approach gives sufficiently accurate results for practical purposes. (Edited author abstract) 13 refs.

**093362 SEISMIC SPECTRA ON SOIL WITH UNCERTAIN PROPERTIES.** Expected spectral ordinates and their standard deviations are computed for ground motions produced by SH waves at the surface of a homogeneous soil formation resting on a half-space of rock. Wave transmission is idealized as linear and one-dimensional. Uncertainties about soil properties are taken into account using various approximations: a Taylor series expansion of the Fourier spectrum magnification factors with different numbers of terms and different intervals for numerical differentiation; discretization of the joint probability density function of the soil properties so as to match its moments up to those of third order including the crossed moments; a discretization that matches up to some fifth-order moments; and a fine numerical integration for the marginal density function of the modulus of rigidity, discretizing the rest of the density function. The latter approach gives sufficiently accurate results for practical purposes. Effects of even moderate uncertainty about soil properties on the statistics of spectral ordinates are found to be decisive. (Author abstract) 13 refs.

**093363 SPECTRAL ESTIMATES OF TELESEISMIC P-WAVE ATTENUATION TO 15 HZ.** NORESS recordings of nuclear explosions in central Asia ( $\Delta = 38^\circ$ ) provide new spectral attenuation estimates for frequencies from about 3 to 15 Hz. Two path spectra, representing propagation losses from the Shagan River and Degelen test sites to southern Norway, are calculated using the double-averaging technique of Bache et al. (1985, 1986). Both paths exhibit less attenuation than previously documented for explosions recorded teleseismically at the UKAEA arrays over the 1- to 8-Hz frequency range. The Shagan and Degelen spectra have somewhat different decay rates, perhaps reflecting variations in average source properties. Since the NORESS data extend to higher frequencies than previously available for attenuation measurements, we compare the NORESS spectral data to published models derived from NORSAR data (1 to 8 Hz) for the same path. The NORESS data support frequency-dependent  $t$  in the 3- to 15-Hz frequency range. The results also demonstrate that extrapolation of attenuation models obtained from longer period data to shorter

periods may not predict the correct spectral levels. Actual high-frequency measurements are needed in order to characterize attenuation behavior at high frequencies. (Edited author abstract) 21 refs.

**093364 MODELING TELESEISMIC SV WAVES FROM UNDERGROUND EXPLOSIONS WITH TECTONIC RELEASE: RESULTS FOR SOUTHERN NOVAYA ZEMLYA.** Detailed forward modeling of long-period shear waves for two large underground explosions at the Southern Novaya Zemlya test site indicates that the appropriate equivalent double-couple orientation for the tectonic release radiation is vertical strike-slip. Incorporating realistic Green's functions using Baag and Langston's (1985b) WKBJ spectral method allows complete modeling of the SV signals. Due to differences in frequency content between the explosion and double-couple SV waveforms, constructive interference occurs more efficiently than destructive interference when the two signals are linearly superimposed. As a result, using tectonic release moments determined from the SH waves and the optimum F factors required to match the SV amplitude patterns, the waveforms produced by the strike-slip and thrust orientations differ substantially at some azimuths. Complete waveform modeling of SV signals can provide improved constraints on tectonic release radiation and explosion source strength. (Edited author abstract) 42 refs.

**093365 P-WAVE AND S-WAVE SEPARATION IN THIN BEDS.** Compressional (P) and shear (S) waves can be separated in vector vertical-seismic profile recordings through the use of multichannel multidimensional filters. These filters have impulse responses that are spatially and temporally infinite, and their application to recordings of finite spatial extent, such as those made in thin beds, results in a truncation error. The use of constrained shift-varying filters helps to minimize this error. The constrained filters are derived under the assumption that most of the energy in the recording is concentrated around a few apparent (vertical) velocities. Implementation of these shift-varying filters requires little additional computation beyond that required by simpler shift-invariant filters. The reduction of truncation error accomplished by this processing scheme is demonstrated with several synthetic data sets. 8 refs.

**093366 NORMAL MOVEOUT REVISITED: INHOMOGENEOUS MEDIA AND CURVED INTERFACES.** The equation of normal moveout is valid for a reflection from the base of a single homogeneous and isotropic bed, but is only an approximation in the real world of multilayered, inhomogeneous media and curved interfaces. Using the theory of geometrical optics. It is possible to find another second-order equation which represents hyperbolas that are also symmetrical about the time axis. However, the centers of these hyperbolas do not coincide with the center of the coordinates, but are shifted along the time axis. This equation is not only more accurate than the usual normal moveout, but its use is more economical on a vector computer because the traditional dynamic correction is a static correction in the Analysis of the focusing depth time. This procedure makes it possible to compute velocities for all the samples of all the stacked traces and produces a velocity section. (Edited author abstract).

de Bazelaire, Eric (Soc Natl Elf Aquitaine, Pau, Fr). *Geophysics* v 53 n 2 Feb 1988 p 143-157.

**093367 RAY BENDING DUE TO STRONG VELOCITY ANOMALIES.** Tomographic methods may be useful in determining localized changes in rock masses if accurate methods of inverting the data can be found. However, in the presence of strong localized anomalies, the underlying assumptions of many tomographic inversion methods break down. In fact, velocity contrasts as low as 15 percent can produce quite distorted raypaths. Even though the raypaths are distorted, the traveltimes on these paths are quite close to those which would arise from the straight-ray assumption. The longer path length is compensated for by higher velocity. As a consequence, blind application of tomographic inversion to data obtained in the presence of strong anomalies can result in an incorrect and distorted but consistent solution. (Author abstract)

**093369 SYNTHESIS SEISMOGRAMS FOR MARINE SEDIMENTS AND DETERMINATION OF POROSITY AND PERMEABILITY.** We present numerical simulations of vertical seismic profiles (VSPs) of marine sediments. The theoretical seismograms, which are computed for vertically incident waves in flat layered poroelastic media, include the effects of dispersion and attenuation predicted by Biot theory. According to Biot theory, fast and slow compressional waves are excited and there is mode conversion at the interfaces. We include this effect in the calculation of reflection and transmission coefficients as an energy-loss mechanism through the slow compressional waves. (Edited author abstract). 15 Refs.

## Analysis

**093370 SYNTHETIC SEISMOGRAMS IN REALISTIC MEDIA: A WAVE-THEORETICAL APPROACH.** In order to interpret seismograms, we should separate the effects of source and medium, which are strongly coupled. The medium effect is usually estimated by computing synthetic seismograms for a model of the Earth. Of course, a three-dimensionally heterogeneous, arbitrarily anisotropic and attenuative medium is the most realistic model, but it requires a great deal of theoretical and numerical effort. At present one- or two-dimensionally layered, isotropic and attenuative media consisting of homogeneous layers are the most productive models for precise waveform analyses of seismograms. A new approach based on the reflectivity method is presented here to compute complete synthetic seismograms in these models. (Edited author abstract) 62 refs.

## Processing

**093371 APPLICATION OF FREQUENCY VARIABLE FILTERS TO SURFACE-WAVE AMPLITUDE ANALYSIS.** The problem of spectral biasing due to frequency domain filtering of surface-wave seismograms is investigated, and the method of frequency variable filters (FVF) is developed to compensate for this bias. As a result, the FVF can significantly improve signal to noise in the filtering process, except at points which require increased frequency domain resolution due to biasing. A detailed comparison of some currently accepted surface-wave filters is made in order to clarify the development of the FVF algorithm. Three long-period, surface-wave seismograms are tested with FVF and compared to two other methods, the multiple filter technique and the phase-matched filter (PMF). Emphasis is placed on finding limitations in all the methods, not on routine processing. Results of the tests show that the FVF and PMF are an improvement over multiple filter technique, in that the results of processing can be diagnosed in both the time and frequency domains. **093373 FREQUENCY DOMAIN COHERENT PROCESSING OF REGIONAL SEISMIC SIGNALS AT SMALL ARRAYS.** It can be shown that most currently-used methods for enhancing regional signals at small arrays are special cases of a more general frequency domain processing scheme designed to optimize the signal/noise power gain for the processor once the signal and noise power spectral matrices are given. The optimum processor makes use of the coherence structures of the signal and noise, and can be simply derived by simultaneous diagonalization of these power spectral matrices. Curiously enough, the optimum processors are not weighted beams but include phase-shifting different from the array beam steers. Such processing schemes can be programmed quite efficiently in the frequency domain and may, in some cases, be more efficient than weighted array beams. (Author abstract) 17 refs.

**093375 MICROZONATION OF A METROPOLITAN AREA.** A method for seismic microzonation of a large metropolitan area (approximately 90×90 km) is examined. It utilizes information on the location of active faults and their relative levels of seismicity, the three-dimensional geometry of the source to station and frequency dependent attenuation, the effects of local amplification of wave amplitudes in terms of the depth of sedimentary deposits beneath the site, and two different scaling procedures in terms of earthquake magnitude and the epicentral intensity. It is shown that these two methods of scaling are consistent, and that both can lead to reliable estimates of uniform risk spectra. The method presented here does not require any new or difficult steps to gather data when compared to other microzonation procedures employed in the United States or abroad. The advantage of the method, however, lies in its ability to properly balance different contributing factors to the seismic risk at a point, in time, space and frequency of strong ground shaking. **093378 ENGINEERING SEISMOLOGY.** With the spread of urban civilization and investment in large engineering projects in seismic regions, the toll to be taken by future earthquakes, and particularly the extent of the damage, are likely to increase. Engineering Seismology emerges, therefore, as an inter-disciplinary branch of engineering, a link between earth sciences and civil engineering, that aims primarily at the minimization, not the elimination, of earthquake risk. Engineering Seismology, in general, provides the data required for proper earthquake risk management, the criteria needed for the selection of safer sites for engineering projects, and in particular provides the engineer with the basic earthquake design ground motions and deformations that structures must survive with economically acceptable damage. The author's central topic is the importance of field observations and measurements in advancing our knowledge of Engineering Seismology. 367 Refs.

**093379 SEISMIC MICROZONING ON SOIL LIQUEFACTION POTENTIAL BASED ON GEOMORPHOLOGICAL LAND CLASSIFICATION.** A simplified procedure without using boring data is proposed for the seismic microzoning on soil liquefaction potential. The geomorphological land classification is adopted as the

index for liquefaction susceptibility, because the classification data are easily available for an area of interest. For each geomorphological unit, the critical peak ground velocity which separates liquefiable from non-liquefiable conditions is investigated based on case histories at about 250 sites during 19 Japanese earthquakes. The critical peak ground velocities at the sites with the same geomorphological unit are almost the same. These critical velocities vary depending on the geomorphological unit. Combining the land classification map and the isoseismal map of an earthquake which represents the distribution of peak ground velocity, the seismic microzoning on liquefaction potential during an earthquake can be readily made. **093380 ATTENUATION OF SEISMIC INTENSITY IN THE BALKAN COUNTRIES.** The parameters of the Gaussian distribution functions (average and standard deviation) of hypocentral distances to selected isoseisms, are presented for Albania, Greece, Bulgaria, Romania, Turkey and Yugoslavia. The results apply for the Medvedev-Karnik-Sponheuer (MKS) intensity, provided that all data is corrected to a unified MKS equivalent intensity as defined by Shebalin et al. (1974). The results should be of general value in macroseismic studies in the Balkan countries, but are essential for the development of microzonation maps when the seismicity is described in terms of the locally available intensity catalogues. Except for the Vrancea region in Romania and south-west Turkey, the observed attenuation of the intensities versus the hypocentral distance is similar to the attenuation of the Modified Mercalli Intensity (MMI) in the western United States of America. This finding should facilitate the use of other empirical scaling relations, developed in California, for various predictions of the characteristics of strong earthquake shaking in the Balkan countries. (Author abstract). 30 refs.

## Australia

**093381 ASSESSMENT OF SEISMIC RISK IN NORTH EASTERN AUSTRALIA.** Research over the last few years has delineated the earthquake history and quantitatively assessed the seismic risk for northeastern Australia. Contrary to common beliefs, the level of seismic activity and consequent seismic risk for this region is comparable with the risk for other well recognized earthquake provinces in Australia. The scene is now set to promote an awareness to the engineering community as to the potential for earthquake damage and to provide seismological information that may be considered relevant to engineering designs. This paper discusses the situation pertaining to a continental (or intra-plate) regime, determines various earthquake parameters (with the emphasis on Richter magnitudes) and relationships between such parameters, and summarises the method of computations for the seismic risk. The research embodies a multidisciplinary approach integrating seismology with geology, tectonics and engineering based on a 118 year history of earthquakes in northeastern Australia. ## Automation

**093382 TOWARDS A KNOWLEDGE-BASED SYSTEM FOR AUTOMATED GEOPHYSICAL INTERPRETATION OF SEISMIC DATA (AGIS).** Geophysical seismic interpretation is part of geophysical oil prospecting. It evaluates and analyzes seismic reflection data aiming at the detection of the position of hydrocarbon reservoirs. This work requires considerable experience and knowledge and must be done by skillful interpreters.

The aim of our research is to develop an expert system, which incorporates some of this geophysical knowledge and which can partly perform a knowledge-based automated geophysical interpretation. In its present state, the system developed can recognize various patterns useful in interpretation. It can also work interactively with an interpreter for improved performance. (Author abstract) 35 refs.

## Instruments

**093383 OPTIMUM DESIGN OF OCEAN BOTTOM SEISMOMETERS.** This paper continues to develop the theory of coupling of ocean bottom seismometers (OBS) to soft sediments and arrive at results suggesting that OBS packages should be designed with: (1) the minimum mass possible, (2) radius of area in contact with the sediment proportional to the cube root of the mass, and the maximum radius less than 1/4 of the shear wavelength, (3) density of the OBS approximately that of the sediment, (4) a low profile and a small vertical cross section with water, and (5) low density gradients, and maximum symmetry about the vertical axis. Agreement of the theory with test data is good; most deviations are reasonable, given limitations of the theory and experiments. The theory also suggests that the coupling frequency, the frequency above which the OBS does not follow the motion of the sediment, is directly proportional to the sediment shear velocity. (Edited author abstract) 23 refs.

**093384 RECONSTRUCTION OF BLOCKY IMPEDANCE PROFILES FROM NORMAL-INCIDENCE REFLECTION SEISMOGRAMS WHICH ARE BAND-LIMITED AND MISCALIBRATED.** We study the inverse problem of determining the impedance of a one-dimensional medium from reflection data which are band-limited and uncalibrated. The problem arises in seismic exploration data processing. We give a brief review of the subject and explain why there is a need to model the data more realistically. We show that if we are given, in addition to the reflection data, some a priori information about the impedance, we can in principle determine the desired unknown. The method incorporates the a priori information about the impedance profile in an optimization problem involving  $L^1$ - and  $L^2$ -norms. From the character of the optima of the minimization, we are able to assess the possibility of absolute calibration of the data, and of estimating the absolute impedance of the medium. Our findings are illustrated with numerous simulations. (Author abstract) 32 refs.

**093385 REFLECTION SEISMOLOGY OVER AZIMUTHALLY ANISOTROPIC MEDIA.** Recent surveys have shown that azimuthal anisotropy (due most plausibly

to aligned fractures) has an important effect on seismic shear waves. The anisotropic effects on different polarization components of vertically traveling shear waves permit the recognition and estimation of very small degrees of azimuthal anisotropy (of order  $\geq 1$  percent), as in an interferometer. Anisotropic effects on traveltime yield estimates of anisotropy which are averages over large depth intervals. Often, raw field data must be corrected for these effects before the reflectors may be imaged; two variations of a rotational algorithm to determine the 'principal time series' are derived. Anisotropic effects on moveout lead to abnormal moveout unless the survey line is parallel to the fractures. Anisotropic effects on reflection amplitude permit the recognition and estimation of anisotropy (hence fracture intensity) differences at the reflecting horizon, i.e., with high vertical resolution. **093386 DISTRIBUTION OF SELENIUM IN HIGH-TEMPERATURE HYDROTHERMAL SULFIDE DEPOSITS AT 13° NORTH, EAST PACIFIC RISE.** 'Black smoker' chimneys and Fe-Cu-rich massive sulfides are found on the axial graben and off-axis seamounts, respectively, of the East Pacific Rise at 13°N. The trace element selenium substitutes for sulfur in solid solution in all sulfide minerals. Electron-microprobe analyses were performed under optimal conditions to obtain a minimum detection-limit (MDL) of 30 ppm for selenium in chalcopyrite, with a calculated precision of 30 ppm. The Se content of the sulfides depends on the physicochemical parameters of the ore solutions during precipitation. High Se values occur in high-temperature mineral assemblages. The highest selenium contents are found in chalcopyrite ( $\approx 2500$  ppm) and in euhedral pyrite ( $\approx 1500$  ppm). For selected samples, the lowest mean concentration of Se in chalcopyrite is 645 ppm. (Edited author abstract) 42 refs.

## Adsorption

**093387 SELENIUM ADSORPTION BY GOETHITE.** For the well-being of human beings and animals, it is necessary to understand the processes that control the mobility and transport of toxic elements in the environment. The behavior of toxic elements is influenced by the redox and pH of the system and by processes such as precipitation and coprecipitation, the formation of organic or inorganic complexes, biological interactions, and adsorption. This paper is concerned with the process of adsorption and how it may influence the mobility of the toxic element, selenium. The adsorption of Se by goethite was studied as a function of time (10 min-24 h), temperature (295.5 and 303.5 K), pH (4-11), particle concentration (3-300 mg/L), total Se concentration ( $0.02-5 \times 10^{-5}$  M), oxidation state [Se(IV) and Se(VI)], and competing anion concentration [anion]/[Se(IV)]=0.25 to 50,000 in order to assess the influence of these factors on Se mobility. 54 refs.

**093388 SORPTION OF SELENIUM(IV) AND SELENIUM(VI) FROM ACID SOLUTIONS BY ORGANO-SILICON ION-EXCHANGERS.** The purpose of this work was to study the possibility of sorption of trace amounts of selenium(IV) and selenium(VI) from acid solutions by organosilicon ion-exchangers. These organosilicon ion-exchangers have higher thermal and chemical stability than organic sulfonated cation-exchangers and ion-exchangers containing sulfhydryl groups (KSG), and

are very effective in relation to a number of precious (Ag, Pt, Pd) and heavy ( $Hg$ ) metals, and also to rare earth elements. It is found that the ion-exchangers studied are most effective with respect to selenium(IV); the ion-exchangers PMMS-2 and PSSK-3 have the highest sorption activity. The optimal conditions for sorption of selenium(IV) were found. 12 refs.

**Amorphous** See Also SEMICONDUCTING SELENIUM—Electric Properties.

**093389 STUDY OF THE ELECTRICAL CONDUCTIVITY OF AMORPHOUS - CRYSTALLINE SELENIUM MIXTURES.** A series of compressed powder samples of a double-phase selenium mixture were prepared with various fractional volumes of amorphous (a) and crystalline (c) phases. The direct current properties of the samples were measured and are discussed. The activation energy was found to decrease from 1.8 eV (for the 90% amorphous-10% crystalline sample) to 0.67 eV (for the 100% crystalline sample). For the same range of fractional volumes, the conductivity  $\sigma_m$  of the mixture at room temperature was found to increase from  $5.5 \times 10^{-13} \Omega^{-1} \text{cm}^{-1}$  to  $5.25 \times 10^{-7} \Omega^{-1} \text{cm}^{-1}$ , and the pre-exponential factor  $\sigma_0$  increased from  $5 \times 10^{-4} \Omega^{-1} \text{cm}^{-1}$  to  $2.75 \Omega^{-1} \text{cm}^{-1}$ . An empirical formula to fit the measured conductivity data over the entire range of the double-phase mixture is proposed. This formula was also tested for massive selenium samples of different degrees of crystallinity (defined from X-ray measurements) and very satisfactory results were obtained. (Author abstract) 17 refs.

**093390 PHENOMENOLOGICAL MODEL OF PHOTOPRECIPITATION IN A-SE COLLOID SOLUTIONS.** An attempt has been made in this study to develop a physical model for the photoprecipitation and photoaggregation effects in amorphous Se(a-Se) colloids. The theory explains in basic terms the experimental time dependence of the precipitated elemental Se concentration. Several kinetic parameters were evaluated by correlating the experiment to theory, subject to strong light intensity and narrow beam approximations. The results were used to quantify and clarify several further features of photoprecipitation in a phenomenological way. (Author abstract) 5 refs.

Peled, A. (Tel-Aviv Univ, Tel-Aviv, Isr); Naot, D. *Colloid Polym Sci* v 265 n 11 Nov 1987 p 986-992.

**093391 INVESTIGATION OF THE PRESSURE DEPENDENCE OF THE ELASTIC CONSTANTS OF AMORPHOUS SELENIUM IN THE VICINITY OF THE GLASS-TRANSITION.** The hydrostatic pressure dependences of the velocities of longitudinal and shear ultrasonic waves propagated in amorphous selenium have been measured as a function of temperature through the glass-transition region. Both  $\partial C_{11}/\partial P$  and  $\partial C_{44}/\partial P$  increase rapidly as temperature is increased, a finding attributed to a combination of increasing vibrational anharmonicity as  $T_g$  is approached from below and to free-volume effects. At room temperature, substantially below  $T_g$ , the thermal Grueneisen parameter is only 1.05 whereas the mean long-wavelength acoustic parameter is 3.0. This arises because the intermolecular volume is much more compressible than the intramolecular volume: the Grueneisen parameters for purely internal modes of vibration are small whereas those for the external modes are larger. (Author abstract) 12 refs.

### Structure

**093393 PHASE RELATIONS AND EQUILIBRIUM COPOLYMERIZATION IN THE Se-S SYSTEM.** The phase relations in the Se-S system were investigated by the appearance of phase method, differential thermal analysis, and differential scanning calorimetry. High purity selenium melts at  $216 \pm 2^\circ\text{C}$ . A peritectic exists at  $85 \text{ at.}\% \text{ Se}$  and  $168 \pm 2^\circ\text{C}$ ; the peritectic isotherm extends from  $92$  to  $73.5 \text{ at.}\% \text{ Se}$ . A temperature minimum of  $102 \pm 1^\circ\text{C}$  exists at a composition of  $35 \pm 1 \text{ at.}\% \text{ Se}$ . High purity sulfur melts at  $114 \pm 1^\circ\text{C}$  and polymerizes at  $160 \pm 2^\circ\text{C}$ . Addition of  $10 \text{ at.}\% \text{ Se}$  lowers the polymerization temperature to  $118 \pm 3^\circ\text{C}$ . The Se-S system shows complete liquid miscibility and in this respect it differs from the majority of selenide type systems that generally show one or more fields of liquid immiscibility. (Edited author abstract) 25 refs.

Boctor, N.Z. (Purdue Univ, West Lafayette, IN, USA); Kullerud, G. *CHEMTECH* v 17 n 8 Aug 1987 p 513-521.

### Thin Films

**093394 STRUCTURAL, MORPHOLOGICAL, AND OPTICAL RECORDING CHARACTERIZATION OF SELENIUM FILMS.** Selenium films obtained by vacuum deposition and hot-wall epitaxy (HWE) were investigated for structural, morphological, and holographic characteristics. Vacuum-deposited Se films, which are generally amorphous, were found to crystallize under an intense beam of an electron microscope. The transmission electron diffraction results indicated that the crystallized phase was  $\beta$ -monoclinic. These films have high transmittance in the visible spectrum and exhibit good exposure characteristics for recording holograms. Parameters such as diffraction efficiency, modulation transfer function, and spatial frequency, determining the exposure characteristics, were evaluated. Films grown by hot-wall epitaxy, however, have different properties. The surface morphology showed growth to needlelike single crystals  $5 \mu\text{m}$  in size, with preferred growth in the (100) direction. These films were gray and exhibited poor transmittance and scattering centers, thus losing their recording properties. X-ray diffraction results of Se films grown by HWE indicated that the crystallized phase was hexagonal in structure. (Edited author abstract) 14 refs.

**093395 ON THE THEORY OF PHOTOADSORPTION KINETICS OF a-SE COLLOIDS: A SIMPLE MODEL FOR THE KINETIC PARAMETERS.** Amorphous selenium (a-Se) films have been deposited from colloid solutions by irradiation with light and the kinetic parameters have been recorded for a wide range of operating conditions. Surface photodeposition (SP) is an adsorption effect by which colloid particles adhere onto

irradiated substrates at the solution interface, to create thin films of continuous composition. Attempt is made to obtain a physical picture of the SP process. For this end, the experimental kinetic law of film growth is used and through a simple but sufficiently realistic model connection to the fundamental physical parameters of the SP mechanisms is made. 11 refs.

**093396 ETUDE DES PROPRIETES DE COUCHES MINCES DE SELENIUM HEXAGONAL DOPEES AU CHLORE.** [Properties of Thin Chlorine-Doped Hexagonal Selenium Films]. Thin films of chlorine-doped selenium were characterized using X-rays, scanning electron microscopy and secondary ion mass spectrometry (SIMS) studies. The conductivity, Hall effect and thermoelectric power variations were measured vs. temperature. A new device for measurements of the thermoelectric power of resistive samples is described. SIMS analysis showed that chlorine was not uniformly distributed in the films. The crystallite size was found to increase when the chlorine concentration decreased and/or when the substrate temperature during deposition increased. The films being polycrystalline, electrical measurements show that only a small fraction of chlorine enters the crystallite and increases the acceptor concentration, while the excess chlorine remains at the grain boundaries. (Author abstract) 23 refs. In French.

**093397 EFFECT OF ULTRATHIN SELENIUM OVERCOAT ON THE STABILITY OF TELLURIUM-BASED OPTICAL RECORDING MEDIA.** An ultrathin selenium overcoat about  $20\text{-}40 \text{ \AA}$  thick was found to be quite effective in retarding both the uniform and the localized degradation rate of tellurium-based optical recording media in room ambient and high humidity and temperature accelerated testing environments. Results from x-ray photoelectron spectroscopy analyses of selenium-overcoated tellurium films and Te-Se alloy films suggested the formation of a high selenium concentration Te-Se alloy for the selenium-overcoated film. The effect of the selenium overcoat is interpreted in terms of the presence of this Te-Se alloy which is capable of retarding both the oxidation and weight loss degradation mechanisms reported previously for thin tellurium films. This interpretation is consistent with the results from the electrochemical studies made on these films in that the open-circuit potential of the selenium-overcoated films corresponds to those for Te-Se alloy films having about 90% Se. ## SELENIUM BISMUTH ALLOYS

### Thin Films

**093398 THERMAL BEHAVIOUR OF  $\text{Se}_{0.995}\text{Bi}_{0.005}$  THIN FILMS.**  $\text{Se}_{0.995}\text{Bi}_{0.005}$  deposited on aluminum (SeBi/Al) and kapton (SeBi/kapton) has been characterized by means of differential thermal analysis. The thermal phenomena such as glass transition temperature, crystallization and melting have been studied. The nature of the substrate on the one hand and the presence of bismuth in selenium on the other hand seem to modify these phenomena. The temperature  $T_g$  corresponding to the binary SeBi alloy is very slightly higher than that of pure selenium. While the nature of the substrate does not modify in such a manner the value of  $T_g$ . The activation energy associated with crystallization for SeBi/Al is higher than the activation energy of SeBi/kapton. A

sharper peak of crystallization occurs in the case of SeBi/kapton reflecting the small size of the crystals. Finally, melting of two phases has been observed in the case of SeBi/Al and a difficult melting in the case of SeBi/kapton. (Edited author abstract) 10 refs.

SOILS—pH Effects.

**Amorphous** See GLASS—Thermal Properties.

## Chemistry

**093399 AQUATIC CHEMISTRY OF SELENIUM: EVIDENCE OF BIOMETHYLATION.** The chemical species of dissolved selenium were examined in surface waters from three sites in the San Joaquin and Imperial Valleys of California. Six dissolved selenium species were identified: the inorganic species selenate and selenite; nonvolatile organic selenides, including seleno amino acids and a dimethylselenium ion; and the volatile methylated forms dimethyl selenide and dimethyl diselenide. Laboratory studies indicate that the nonvolatile dimethylselenium ion can be transformed into volatile dimethyl selenide at neutral pH, providing a pathway for the in situ production of dimethyl selenide in natural waters. Geochemical flux calculations indicate that outgassing of dimethyl selenide may be an important removal mechanism for dissolved selenium from aqueous systems. (Edited author abstract) 22 refs.

Cooke, Terence D. (Univ of California, Santa Cruz, CA, USA); Bruland, Kenneth W. *Environ Sci Technol* v 21 n 12 Dec 1987 p 1214-1219.

## Electrodeposition

**093400 NATURE OF THE SITES OF ELECTRON GENERATION ON SELENIUM SURFACES DURING ELECTRODEPOSITION FROM STRONGLY ACIDIC ELECTROLYTES.** The nature of the sites of electron generation was studied on selenium surfaces in strongly acidic electrolytes. It is shown that in strongly acidic electrolytes, adsorbed oxides of selenium are the SEG (Sites of Electron Generation) on the electrode surface. They are stable only in strongly acidic media (pH < 0.7) when there is a large excess of SeO<sub>2</sub> present in the solution. In electrolytes with a lower concentration of hydrogen ions, the adsorbed surface oxides dissolve, the sites of electron generation disappear, and the rate of the electrochemical reaction decreases drastically. (Edited author abstract) 9 refs.

## Environmental Impact

**093401 ACCUMULATION OF SELENIUM IN CROPS GROWN ON SLUDGE-TREATED SOIL.** Uptake by barley, Swiss chard and radish of Se from composted Los Angeles County sewage sludge applied to land was studied in a long-term field study. Sludge was applied at 0, 225.5, 45, 90, and 180 Mg/ha per year for 8 to 10 yr and the data reported here are for the last year of the study. Total surface soil Se increased with the highest rate of sludge addition from < 0.1 mg/kg in the control soil to 1.2 mg/kg. Only 13 to 25% of the sludge-applied Se could be accounted for in the 0- to 15-cm depth of incorporation and there was no measurable Se in the subsoil to 150 cm. There was little or no measurable uptake of Se by barley leaf and grain at the level of detection of this study, and there were also no significant increases in chard or radish Se concentrations with sludge addition. Selenium concentrations in chard (0.05-0.11 mg/kg) were severalfold lower than those in radish. (Edited author abstract) 18 refs.

Logan, T.J. (Ohio State Univ, OH, USA); Chang, A.C.; Page, A.L.; Ganje, T.J. *J Environ Qual* v 16 n 4 Oct-Dec 1987 p 349-352.

**093402 BIOGEOCHEMICAL CYCLING OF SELENIUM IN THE SAN JOAQUIN VALLEY, CALIFORNIA, USA.** Subsurface agricultural drainage waters from western San Joaquin Valley, California, were found to contain elevated concentrations of the element selenium in the form of selenate. In 1978, these drainage waters began to replace previous input to Kesterson Reservoir. In the 1983 nesting season, unusual rates of deformity and death in embryos and hatchlings of wild aquatic birds occurred at the refuge and were attributed to selenium toxicosis. Features necessary for contamination to have taken place included geologic setting, climate, soil type, availability of imported irrigation water, type of irrigation, and the unique chemical properties of selenium. (Edited author abstract) 103 refs.

Presser, Theresa S. (US Geological Survey, Menlo Park, CA, USA); Ohlendorf, Harry M. *Environ Manage* v 11 n 6 Nov 1987 p 805-821.

**093403 SELENIUM UPTAKE BY SOME AGRICULTURAL CROPS FROM CENTRAL CALIFORNIA SOILS.** Greenhouse experiments were conducted to study Se uptake and partitioning by crops grown in five California soils of differing physical and chemical properties. Alfalfa (*Medicago sativa* L.), barley (*Hordeum vulgare* L.), beet (*Beta vulgaris* L.), and tomato (*Lycopersicon esculentum* Mill.) were grown in soil to which 0, 0.5, and 1.5 mg Se(VI) kg<sup>-1</sup> was added. Alfalfa was also grown in four additional soils to which 0, 0.5, 1.5, and 3.0 mg Se(VI) kg<sup>-1</sup> had been added. Plants were grown to maturity, separated into plant parts and analyzed for yield and tissue Se. For the barley, beet, and tomato, the edible portion of the plant contained much less total Se than the generally inedible plant parts. The presence of soluble SO<sub>4</sub><sup>2-</sup> in the soil was the major soil factor in determining Se accumulation by plants. Alfalfa grown in low-SO<sub>4</sub><sup>2-</sup> soil accumulated Se to a concentration 10 to 20 times greater (> 1000 mg Se kg<sup>-1</sup>) than plants growing in high-SO<sub>4</sub><sup>2-</sup> soil (< 100 mg Se kg<sup>-1</sup>). When exposed to Se(VI) in the root zone, all plants tested were capable of accumulating Se to concentrations potentially harmful to animals. (Author abstract) 22 refs.

Wan, H.F. (Acad Sinica, Nanjing, China); Mikkelsen, R.L.; Page, A.L. *J Environ Qual* v 17 n 2 Apr-Jun 1988 p 269-272.

**093404 GROWTH AND UPTAKE OF SELENIUM BY SWISS CHARD IN ACID AND NEUTRAL SOILS.** The absorption of Se by plants in acid and neutral soils in relation to the concentration and chemical form of Se added was studied. Selenate-Se added to an acid in amounts equal to or greater than 1.0 mg kg<sup>-1</sup> significantly reduced yields of Swiss chard (*Beta vulgaris* L. var. cicla). Selenite-Se, however, added to the acid soil at levels up to 2 mg kg<sup>-1</sup> did not affect yields. Likewise, yields were also unaffected when selenite or selenate was added alone or in combination to a neutral soil at levels up to 2 mg Se kg<sup>-1</sup>. Amounts of Se absorbed by plants from soils where selenate was added were greater than where selenite was added. Selenate added to the soils was, in part, reduced to selenite during the growth period. (Author abstract) 12 refs.

**093405 DISTRIBUTION AND MOBILITY OF SELENIUM AND OTHER TRACE ELEMENTS IN SHALLOW GROUNDWATER OF THE WESTERN SAN JOAQUIN VALLEY, CALIFORNIA.** Samples of shallow groundwater that underlies much of the irrigated area in the western San Joaquin Valley, CA, were analyzed for various major ions and trace elements, including selenium. Concentrations of the major ions generally were similar for groundwater collected in the two primary geologic zones - the alluvial fan and basin trough. Selenium concentrations are significantly higher in the

groundwater of the alluvial-fan zone than in that of the basin-trough zone. The concentrations of oxyanion trace elements were significantly correlated with groundwater salinity, but the correlations between selenium and salinity and between molybdenum and salinity were significantly different in the alluvial-fan geologic zone. Study conclusions are discussed. (Edited author abstract) 33 refs.

## Phase Transitions

**093406 CONTROL OF PHASE TRANSITION IN TaSe<sub>3</sub>.** Stabilization factors of the high and low temperature phases of TaSe<sub>3</sub> are investigated. The low temperature phase is stabilized by zirconium or titanium impurity. The high temperature phase is stabilized by oxygen impurity. Without oxygen impurity, the low temperature phase is stable up to decomposition temperature and the phase transition is completely suppressed by zirconium impurity. (Author abstract) 8 refs.

## Synthesis

**093407 NEW TRANSITION METAL SILICOSELENIDES POSSESSING CdI<sub>2</sub>-TYPE STRUCTURES.** Three different kinds of first-row transition metal silicoselenides having CdI<sub>2</sub>-related structures have been synthesized. Vanadium and chromium form VSiSe<sub>3</sub> and Cr<sub>1+x</sub>SiSe<sub>3</sub> which are similar to MPSe<sub>3</sub>, crystallizing in a hexagonal structure. Manganese forms Mn<sub>3/2</sub>SiSe<sub>3</sub>, which is isostructural with Mn<sub>3/2</sub>SiTe<sub>3</sub>. With Fe, Co and Ni, a new type of silicoselenide with the formula MSi<sub>2</sub>Se<sub>4</sub> (M = Fe, Co or Ni) is obtained. These solids crystallize in the CdI<sub>2</sub>/Cr<sub>3</sub>S<sub>4</sub> structure, where M atoms and Si-Si pairs occupy the cation positions. (Author abstract) 12 refs.

## Toxicity

**093408 ACUTE TOXICITY OF INORGANIC SELENIUM TO DAPHNIA MAGNA (STRAUS) AND THE EFFECT OF SUB-ACUTE EXPOSURE UPON GROWTH AND REPRODUCTION.** The acute toxicities of sodium selenite (Na<sub>2</sub>SeO<sub>3</sub>) and sodium selenate (Na<sub>2</sub>SeO<sub>4</sub>) to *Daphnia magna* were determined in defined culture at 22°C. For adults, the 48-h LC<sub>50</sub> values were 0.68 ppm selenium as selenite and 0.75 ppm selenium as selenate. Juveniles were more sensitive, with a 48-h LC<sub>50</sub> of 0.55 ppm selenium as selenate. Eggs and embryos were found to be much less sensitive, with a 72-h LC<sub>50</sub> of 1.4 ppm selenium as selenate. Sub-acute exposure of *D. magna* to sodium selenate caused suppression of growth over instars 1-5 and reduced egg production in instar 9 when adults were exposed to test solutions from instar 6 onwards. These sublethal effects were found at concentrations in the range proposed as suitable for the use of selenium in the amelioration of mercury contamination. (Author abstract) 25 refs.

## SELENIUM INDIUM ANTIMONY ALLOYS

## Thin Films

**093410 SELENIUM-INDIUM-ANTIMONY ALLOY FILM FOR ERASABLE OPTICAL DISKS.** A new type of crystal phase change was found in selenum-indium-antimony alloy film, which is a unique material. The phase change occurs reversibly between two different crystal states when the film is irradiated with laser pulses, resulting in different optical reflectivities. An erasable optical disk using this film has good carrier-to-noise-ratio of 45 db, moderate recording sensitivity and long media life, but erasable cycles still vary from between  $10^3$  and  $10^6$  times at present. Though there remain some problems to be solved, the disk is nearly ready for practical use, and as such is promising. A proposed model of the phase-change mechanism is discussed. (Edited author abstract) 9 refs.

## Analysis

**093412 QUASIPARTICLE CALCULATION OF VALENCE BAND OFFSET OF  $\text{AlAs-GaAs}$  (001).** A

first principles quasiparticle theory for band offsets of heterojunctions is developed and used to compute the valence band offset  $\Delta E_v$  for the prototypical  $\text{AlAs-GaAs}$  (001) interface. The result  $\Delta E_v = 0.53 \pm 0.05$  eV is in good agreement with recent experimental values and in particular with the most recent photoluminescence data  $\Delta E_v = 0.56 \pm 0.03$  eV for an MBE grown sample. We show that there is a substantial many-body correction of 0.12 eV to the value of the valence band offset calculated using local density functional theory. (Author abstract) 32 refs.

**093413 DEEP ELECTRON TRAPS IN  $\text{AlAs-GaAs}$  SUPERLATTICES AS STUDIED BY DEEP-LEVEL TRANSIENT SPECTROSCOPY.** Deep electron traps in Si-doped  $\text{AlAs-GaAs}$  superlattices (SLs) grown by MBE have been investigated using deep-level transient spectroscopy (DLTS). The concentration of the characteristic electron trap (E2 trap) in the SLs increases upon decreasing the period of SL and increasing the Si doping concentration. The E2 trap concentration for uniformly Si-doped SLs is more than one order higher than that for SLs doped selectively at the middle part of each  $\text{AlAs}$  and  $\text{GaAs}$  layer. The E2 traps have properties similar to the so-called DX centers in  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ , and they exist only in the  $\text{AlAs-GaAs}$  interfaces. The different activation energies of the traps in SLs and  $\text{Al}_{0.3}\text{Ga}_{0.7}\text{As}$  can be explained in terms of carrier emission from the E2 trap to the mini-band levels of the SLs and to the conduction band minimum of the alloys, respectively. (Author abstract) 11 refs.

## Defects

**093415 CONTRIBUTION A L'ETUDE DES FAUTS DE CROISSANCE PAR EJM A L'AIDE DE LA PHOTOLUMINESCENCE ET LA MICROSCOPIE AUGER.** [Contribution to Study of Growth Defects in Molecular Beam Epitaxy Aided by Photoluminescence and Auger Microscopy]. Morphological growth defects, so-called oval defects, are investigated in MBE Si doped  $\text{Al}_x\text{Ga}_{1-x}\text{As}$   $x = 0.30$  layers by photoluminescence topography (PLT) and by Auger electron spectroscopy (AES). The photoluminescence emission peak of these

defects lies between 0.78 and 0.90  $\mu\text{m}$  corresponding to an Al concentration between 0 and 15%. The intensity of this emission is anomalously high which could possibly be explained by a local confinement. Most oval defects present essentially the same behavior when analyzed by PLT, while scanning Auger microscopy reveals morphological and compositional differences. A variation in the Al and Ga concentration as well as the presence of certain impurities (O-In) are observed. These results give further support to the fact that gallium oxides play a major role in the formation of some oval defects and that some others may contain different impurities. (Author abstract) 6 refs. In French.

**093416 ELECTRICAL PROPERTIES OF CADMIUM AND ZINC DOPED  $\text{CuAlS}_2$ .** The aim of this note is to study the electrical properties of cadmium and zinc doped  $\text{CuAlS}_2$  single crystals. Copper (99.999 percent), aluminium and sulfur (99.999 percent) were used as starting materials for obtaining the  $\text{CuAlS}_2$  ternary compound. The stoichiometric quantities of the starting elements were sealed under high vacuum (up to  $10^{-3}$  Pa) in a Nb crucible held in quartz ampoule. The synthesis was carried out by the direct melting method in a vertical furnace with vibration. To achieve equilibrium the compound obtained was homogenized by subsequent annealing. X-ray diffraction studies showed that the resulting material was of single phase. 5 Refs.

**093417 HOT ELECTRON DISTRIBUTION AND TRANSPORT IN  $\text{AlGaAs/GaAs/AlGaAs}$  QUANTUM WELLS.** We report experimental studies of hot electron distributions and energy relaxations in modulation doped  $\text{AlGaAs/GaAs/AlGaAs}$  multiple quantum wells. We have measured high field-dependent photoluminescence spectra with different MQWs. We discuss two-dimensional electron distributions and hot electron-phonon interactions, i.e. electron temperatures depending on two-dimensional electron density and quantum well structures. In the highly doped MQW, the electron temperature increased significantly from low electric fields. These experimental results are discussed from the aspect of two-dimensional electron-phonon interactions. (Author abstract) 7 refs.

**Electric Field Effects** See Also SEMICONDUCTING GALLIUM ARSENIDE—Electric Field Effects.

**093418 ELECTRON VELOCITY AT HIGH ELECTRON FIELDS IN  $\text{AlGaAs/GaAs}$  MODULATION-DOPED HETEROSTRUCTURES.** We have measured the electron velocity in low-doped  $\text{GaAs}$  and in  $\text{AlGaAs/GaAs}$  modulation-doped heterostructures at electric fields up to 8000 V/cm at both 300 and 77 K. In order to avoid the charge domain formation which occurs in dc measurements at these fields, this measurement uses 35 GHz radiation to supply the electric field. These measurements indicate that the peak velocity for electrons in the heterostructures is lower than electrons in bulk low-doped  $\text{GaAs}$ . This result is explained in terms of modified intervalley transfer, real space transfer, and an enhanced scattering with polar optical phonons. (Author abstract) 20 refs.

State Electron v 31 n 3-4 Mar-Apr 1988, Hot Carriers in Semicond, Boston, MA, USA, Jul 20-24 1987 p 337-340.

**093419 HIGH FIELD HOT ELECTRON TRANSPORT THROUGH  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  MULTIQUANTUM WELL SUPERLATTICES.** We report the measurement of the high electric field hot electron mean free path  $L$  for transport through  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  multiquantum well superlattices by fabricating a novel detector whose  $\gamma = 10\mu\text{m}$  infrared sensitivity critically depends on hot electron transport. We find  $L$  to be  $L = 4500$  Angstrom for a 50 period superlattice composed of 72 Angstrom GaAs quantum wells separated by 133 Angstrom  $\text{Al}_{0.3}\text{Ga}_{0.7}\text{As}$  tunneling barriers (i.e.,  $L = 22$  periods). We have achieved an avalanche gain of 300% at  $10\mu\text{m}$  in these quantum well superlattices. The electrons are generated by resonant intersubband tunneling and then avalanche by hot electron impact ionization of carriers out of the quantum wells. By analyzing these measurements we find a highly nonthermal peaked electron distribution with a relatively narrow energy width of 60 meV. (Edited author abstract) 19 refs.

**093420 MAGNETORESISTANCE EFFECT IN  $\text{AlGaAs/GaAs}$  TWO-DIMENSIONAL ELECTRON GAS STRUCTURES AT ROOM TEMPERATURE.** Room temperature magnetoresistance measurements have been made on a number of  $\text{AlGaAs/GaAs}$  two-dimensional electron gas structures in fields of up to 7 Tesla. These wafers exhibit varying degrees of conduction in the  $\text{AlGaAs}$  in parallel with the 2-D electron gas which is formed at the heterojunction. By making the assumption of a single, energy-independent scattering time for each conducting channel, the magnetoresistance data are well fitted by the two band model, giving values of the sheet electron density in the 2-D electron gas at 300 K in with the results of Shubnikov-de Haas measurements at 4.2 K, even in the presence of significant parallel conduction. An upper limit on the error associated with this assumption in the case of the 2-D electron gas can be estimated by studying samples with minimal parallel conduction. (Edited author abstract) 13 refs.

**093421 CHARGE TRAPPING IN  $n\text{-Al}_x\text{Ga}_{1-x}\text{As}$  'INSULATORS' AND RELATED DEVICE INSTABILITIES.** In some devices based on  $\text{GaAs/Al}_x\text{Ga}_{1-x}\text{As}$  heterostructures, the  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  plays the role of a wide band gap 'insulator'. These devices are therefore excellent systems for studying charge trapping in  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ . It is poorly understood property of  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  that incorporation of any n-type dopant results in the formation of a deep electron trap, the DX center. Recent experiments on heterostructure devices have probed both thermal and athermal (hot electron) capture and emission by the DX center. By observing the trapping behavior as the composition (Al mole fraction) of the alloy is varied, the relationship between the trap level and the band structure of the host material has been clarified. A remarkable result is the observation of electron trapping at alloy compositions where the trap state is resonant with the conduction band. (Author abstract) 37 refs.

## Electronic Properties

**093422 MEASUREMENT OF 'MATERIAL' PARAMETERS IN MULTI-QUANTUM-WELL STRUCTURES.** Multi-quantum-well (MQW) structures can be

regarded as new materials whose properties are determined by the well and barrier thicknesses  $L_z$  and  $L_b$  and the well depth (which is composition dependent). Measurements of  $L_z$ ,  $L_b$  and  $x$  are reported for 16 MQW samples grown by molecular beam epitaxy in the  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  system. Results from x-ray diffraction, photoluminescence excitation spectroscopy and transmission electron microscopy are found to compare well with each other and with values predicted from MBE growth conditions. (Author abstract) 45 refs.

**093423 CALCULATIONS OF BOUND STATES IN THE VALENCE BAND OF  $\text{AlAs/GaAs/AlAs}$  AND  $\text{AlGaAs/GaAs/AlGaAs}$  QUANTUM WELLS.** A realistic pseudopotential complex-band-structure approach to the calculation of bound states in semiconductor quantum wells is described. The method is applied to the determination of bound-state energies and charge densities in the valence band of (100)  $\text{AlAs/GaAs/AlAs}$  and  $\text{Al}_{0.3}\text{Ga}_{0.7}\text{As/GaAs/Al}_{0.3}\text{Ga}_{0.7}\text{As}$  isolated quantum wells as functions of well width. Our results suggest the existence of additional structure in the optical spectra of quantum wells at widths corresponding to regions in which there is substantial hybridization of light- and heavy-hole bound states. (Author abstract) 25 refs.

**093424 ENERGY RELAXATION OF 2D ELECTRONS AT AN  $\text{AlGaAs/GaAs}$  HETEROJUNCTION AT HELIUM TEMPERATURES.** The peculiarities of 2D electron gas heating are derived from the comparison of temperature and field dependences of galvanomagnetic effects for one or two occupied size-quantized subbands. The main energy relaxation mechanism at helium temperatures is shown to be the scattering by piezoelectric potential of acoustic phonons. Experimental data and theory show that while the carrier density increases, the temperature dependence of energy loss rate changes due to contribution of electrons in second subband to the energy relaxation processes. (Author abstract) 8 refs.

**093425 RELAXATION OF THE NON-POLAR (1010) SURFACES OF WURTZITE  $\text{AlN}$  AND  $\text{ZnS}$ .** Using the pseudo-function method and local density theory, we minimize the total energy of the (10 $\bar{1}$ 0) surfaces of  $\text{AlN}$  and  $\text{ZnS}$ , within the context of a Rigid Rotation Model. We predict that the surface anions rotate inward toward the bulk through very small angles (in contrast to the anions of the (110) surface of GaAs, which rotate outward through large angles,  $\omega \approx 29^\circ$ ). Thus, to an adequate approximation, the (10 $\bar{1}$ 0) surfaces of these relatively ionic wurtzite semiconductors do not relax. (Author abstract) 11 refs.

**093427 GROWTH PROPERTIES OF  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  GROWN BY MOVPE USING TEG AND TMA.** Correlations of metalorganic gas flow rate ratio with solid phase composition and the growth rate of MOVPE-grown  $\text{AlGaAs}$  using TEG and TMA are investigated. The  $\text{AlGaAs}$  growth rate is low compared to the sum of individually grown GaAs and AlAs growth rates, and solid phase composition differs from that calculated from their growth rate ratios. These characteristics result from variations in GaAs and AlAs growth rates with vapor phased composition. The correlations among growth properties can be explained by considering the reaction between metalorganic gas sources which reduces the amount of metalorganics contributing to the growth. (Author abstract) 7 refs.

**093428 ARSENIC PRESSURE DEPENDENCE OF COMPOSITION  $x$  IN  $\text{Al}_x\text{In}_{1-x}\text{As}$  GROWN BY MOLECULAR BEAM EPITAXY.** The dependence of the composition  $x$  of  $\text{Al}_x\text{In}_{1-x}\text{As}$  on the arsenic pressure and substrate temperature in molecular beam epitaxy is investigated. At a growth temperature of  $540^\circ\text{C}$ , the composition scarcely depends on the arsenic pressure, but at  $580^\circ\text{C}$  the Al composition decreases with increasing arsenic pressure under a constant flux ratio of group III elements. The dependence of composition  $x$  on the arsenic pressure and substrate temperature can be explained semiquantitatively using a modified thermodynamical model. (Author abstract) 9 refs.

Nakagawa, Tsuyoshi (Osaka Univ, Ibaraki, Jpn); Gonda, Shun-ichi; Emura, Shuichi; Shimizu, Saburo. *J Cryst Growth* v 87 n 2-3 Feb 1988 p 276-280.

**093429 CHARACTERIZATION OF  $\text{AlGaAs/GaAs}$  HETEROSTRUCTURES GROWN IN A MULTI-CHAMBER OMVPE APPARATUS.** Organometallic vapor phase epitaxial (OMVPE) growth of compound semiconductor is carried out in a multichamber apparatus under reduced hydrogen pressure. Provided the transit times of the reactant fluxes through the reaction cell are small compared to time required for their fluxes to broaden spatially by diffusion, a condition achievable at low pressure, each reactant may be localized to a portion of reaction cell. By positioning substrates by rotation in these localized growth zones with the appropriate combination of the sources; trimethylgallium, trimethylaluminum, and arsine, abrupt  $\text{AlGaAs/GaAs}$  heterostructures are formed. With this technique  $\text{AlAs/GaAs}$  superlattices of 12 Å period are observed with transmission electron microscopy (TEM). Also Raman spectroscopy and photoluminescence are used to characterize the effects of rotation speed and the growth rate on the resulting heterostructures. By combining these superlattices into separate confining laser structures high efficiency, low threshold injection lasers are demonstrated. 14 refs.

**093430 CRITICAL MISORIENTATION MORPHOLOGY IN  $\text{AlGaAs}$  AND  $\text{GaAs}$  GROWN BY ATMOSPHERIC-PRESSURE MOCVD ON MIS-ORIENTED SUBSTRATES.** This work describes a study of misorientation effects in the growth of  $\text{AlGaAs}$  and  $\text{GaAs}$  by atmospheric-pressure MOCVD. The pronounced rough morphology reported here was observed at  $700^\circ\text{C}$  using misoriented (100) GaAs substrates with a

high density of induced nucleation flaws. Growth on these substrates was characterized by faceted defects with a well-defined angle between singular-plane trends and clustered monatomic step risers. Long-range morphology on a GaAs epitaxial layer in the form of terraces similar to those seen in LPE was also observed for growth at 700°C on a well-prepared (100) substrate. The observation of long-range surface morphology and critical misorientation effects demonstrates that near-equilibrium growth conditions have been found in atmospheric-pressure MOCVD where the step surface energy is lowered by a long-range morphology of treads and risers, for growth on slightly misoriented (100) substrates. (Edited author abstract) 24 refs.

**093431 THERMODYNAMIC STABILITY AND REACTIVITY OF AISB AND THEIR RELATIONSHIP TO CRYSTAL GROWTH.** The vapor pressure, species concentration and reactivity of AISB is modeled thermodynamically using the newly-described sticky trust region technique, STRT, for free energy minimization. The conditions chosen include oxygen and hydrogen concentrations appropriate to Czochralski crystal growth in SiO<sub>2</sub>, CBN, Al<sub>2</sub>O<sub>3</sub> and BeO crucibles and growth in the absence of a crucible. Results are compared with crystal growth experiments where appropriate. At the melting point the principal vapor species is Sb<sub>2</sub> with a total vapor pressure of approx. 10<sup>-3</sup> atm, which is about 10<sup>2</sup> larger than for GaSb. The results agree with the experimental data of Sirota and Golodushko. Reaction with the crucible is predicted for SiO<sub>2</sub> and BN in agreement with crystal growth experiments and also with C, where the slow kinetics of vitreous carbon reactions make it possible to use it for crucibles. Al<sub>2</sub>O<sub>3</sub> and BeO are predicted to be inert. Preliminary crystal growth results confirm these results and these materials are recommended for further investigation. The results indicate that thermodynamic 'testing' of crucibles is an appropriate crystal growth strategy. (Author abstract) 12 refs.

**093432 GROWTH OF AlGaAs AND GaAs BY ATMOSPHERIC-PRESSURE MOCVD ON LENTICULAR SUBSTRATES.** This work describes a study of the growth by atmospheric-pressure MOCVD at 650-700°C of AlGaAs and GaAs on lens-shaped substrates which sample surface misorientations up to 22° from the (100). Only visually smooth growth and no change in the band-edge PL wavelength were observed for small misorientations from the (100) plane under these growth conditions, in contrast to readily observed rough morphology patterns and PL band-edge shifts in MBE. Patterns of rough growth due to microscopic point defects associated with specific crystalline orientations were observed for both MOCVD-grown AlGaAs and GaAs films for surface misorientations greater than 10°. (Edited author abstract) 14 refs.

## Impurities

**093433 FLUORESCENCE EXAFS STUDY OF AlGaAs DOPED WITH Se DONOR IMPURITIES.** We performed extended x-ray absorption fine structure measurements on Al<sub>0.38</sub>Ga<sub>0.62</sub>As:Se in order to investigate the lattice relaxation accompanying the existence of the deep level. The local structure of Se donor impurities was observed by monitoring the SeK<sub>α</sub> fluorescence yield. A small glancing angle arrangement was applied to suppress the effects of both Ga and As K<sub>α</sub> fluorescence x-rays. The nearest-neighbor distances around Se were not influenced by the existence of the deep level. (Author abstract) 20 refs.

**093435 DETERMINATION OF THE PHOTOIONIZATION THRESHOLD OF THE DEEP DONOR IN Al<sub>0.33</sub>Ga<sub>0.67</sub>As:Si.** Photoionization of the DX center in Si-doped Al<sub>0.33</sub>Ga<sub>0.67</sub>As has been studied by means of photoconductivity. The optical cross-section shows a threshold at hν=200 Mev and relative maxima (shoulders) around 400, 600, 950, and 1700 Mev. The results throw doubt on the validity of the large lattice relaxation model, generally accepted for this class of centers. They can be well accounted for by the small lattice relaxation model, recently proposed by the authors. (Author abstract) 15 refs.

## Microscopic Examination

**093436 STRUCTURE OF AlGaAs/GaAs MULTILAYERS IMAGED IN SUPERLATTICE REFLECTION.** A new transmission electron microscope method is reported where plan-view samples of Al<sub>0.3</sub>Ga<sub>0.7</sub>As/GaAs multilayers in (001) orientation and with a modulation wavelength of 210 Å are imaged using superlattice reflections. The results, obtained using both a large-angle diffraction technique and direct dark-field imaging, provide an accurate measurement of the multilayer period and also suggest the occurrence of local fluctuations in period, possibly of monolayer dimensions, which differ along [110] and [11̄0] directions. The method also provides some information on the composition profile in multilayers. (Author abstract) 3 refs.

**093437 DYNAMIC SWITCHING CHARACTERISTICS OF PHOTOLUMINESCENCE BY AN ELECTRIC FIELD IN AlGaAs QUANTUM WELL STRUCTURES.** Transient photoluminescence measurements for

pulsed electric field at room temperature on AlGaAs quantum well structures have been carried out to clarify the characteristics of luminescence switching by an electric field. With our method, the radiative lifetime and non-radiative lifetime can be separately evaluated. Luminescence switching by electric field shows a high speed capability that is free from lifetime limitation. Based on the relationships between radiative and nonradiative processes, the intensity modulation of luminescence under the condition of a constant carrier density is demonstrated. (Author abstract) 11 refs.

**093439 PERSISTENT PHOTOCONDUCTIVITY IN FREE-STANDING LAYERS OF n-AlGaAs.** Persistent photoconductivity has been observed in free-standing epitaxial layers of n-AlGaAs. Values of Hall electron mobility and concentration have been measured. The results demonstrate that the major part of persistent photoconductivity is a bulk effect, characteristic of AlGaAs, and it does not require the presence of a heterointerface with GaAs. Electron mobility is about one-fourth of the theoretically calculated value; therefore, a reassessment of alloy scattering strengths is required. (Edited author abstract) 18 refs.

**093441 EFFECT OF HOT PHONONS AND COUPLED PHONON-PLASMON MODES ON SCATTERING-INDUCED NDR IN QUANTUM WELLS.** We have extended our Monte Carlo simulation of scattering-induced NDR in Al<sub>0.8</sub>Ga<sub>0.2</sub>As/GaAs quantum wells by including (a) the effect of hot phonons (b) coupled phonon-plasmon modes (c) degeneracy. Hot phonons were modeled using a phenomenological lifetime which we ranged from 3ps to 10ps. Coupled modes were

modelled in the antiscreeing approximation. Bulk-like modes were assumed in both cases. NDR is quenched if the phonon lifetime exceeds 7ps, but is little affected if the lifetime is 3ps. The effect of coupled modes is appreciable at a doping density of  $10^{18}\text{cm}^{-3}$ , virtually eliminating NDR, but at  $10^{17}\text{cm}^{-3}$  the effect is much smaller. Including degeneracy has only a small effect on the results. We conclude that NDR is still possible at electron densities around  $10^{17}\text{cm}^{-3}$ . (Author abstract) 9 refs.

**093447 SIMULATIONS OF NONLINEAR TRANSPORT IN  $\text{AlGaAs/GaAs}$  SINGLE WELL HETEROSTRUCTURES.** There have been, efforts devoted to novel APD structures which take advantage of heterojunctions. Unlike bulk structures, the performance of these devices is based on nonlinear transport perpendicular to heterojunctions and involves details of band structures and band edge discontinuities. Theoretical investigations have mostly been devoted to the macroscopic quantities rather than microscopic processes. We present a numerical study of nonlinear transport across heterointerfaces in strong electric fields and concentrate on the details of the energy distribution of electrons. The specific structure under consideration is a generic  $\text{AlGaAs/GaAs}$  single well structure as shown. (Edited author abstract) 8 refs.

## Vapor Deposition

**093448 MOVPE GROWN  $\text{Al}_x\text{Ga}_{1-x}\text{As/GaAs}$  HETEROSTRUCTURES.** The factors controlling interface quality of MOVPE grown  $\text{Al}_x\text{Ga}_{1-x}\text{As/GaAs}$  double quantum wells (QW) are discussed with reference to a monolayer step propagation model for growth. To illustrate the application of MOVPE QW structures, high electron mobility transistors (HEMTs) and a multiple quantum well (MQW) device are briefly reviewed. (Author abstract) 5 refs.

Roberts, J.S. (Univ of Sheffield, Sheffield, Engl). *Chemtronics* v 2 n 2 Jun 1987 p 78-82.

**093449 CHLORIDE VPE OF  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  BY THE HYDROGEN REDUCTION METHOD USING A METAL AL SOURCE.** VPE of  $\text{AlGaAs}$  by the chloride transport method using separate Al and Ga metals has been demonstrated for the first time.  $\text{AsCl}_3$  instead of toxic  $\text{AsH}_3$  was used as the arsenic source. Mirror-like surfaces with growth rates of 1-2  $\mu\text{m/hr}$  were obtained. Background doping levels range in the order of  $10^{18}\text{cm}^{-3}$ , probably due to the reaction between  $\text{AlCl}_3$  and the quartz reactor. Band-edge emissions were observed in the photoluminescence spectra. (Author abstract) 9 refs.

## SEMICONDUCTING ANTIMONY

### Radiation Effects

**093450 DEFOCUSING OF ATOMIC KNOCK-ONS IN CRYSTALS LOW LOCAL SYMMETRY OF STRUCTURAL ELEMENTS.** An essential condition for the high radiation stability (RS) of semiconductors and dielectric materials is the fulfillment of the inequality  $r_0 > l_f$  for all crystallographic directions, where  $r_0$  is the radius of the instability zone of the pair vacancy interstitial atom and  $l_f$  is the path length of a dynamic crowdion. Besides structures possessing suppressed focusing of atomic knock-ons resulting from the lack of focusing lenses, there are structures whose local symmetry lowering leads to the suppression of due simple focusing due to the goffering of atomic chains as well as the suppression of additional focusing due to the asymmetric defocusing lenses. Thus the distortion of lattice structures causes a diminution of  $l_f$  and an improvement of RS in such materials when compared with undistorted ones. A higher radiation stability should also be present in those crystals where focusing is possible only in some crystallographic directions. The aim of the investigations has been the experimental test of this statement. The following single crystal semiconductor materials were investigated: SnSe having a distorted NaCl lattice and SnSe<sub>2</sub> possessing a layer lattice of the CdI<sub>2</sub> type were one half of the octahedral sites is unoccupied in the hexagonal close-packed lattice of iodine ions. 11 refs.

## SEMICONDUCTING ANTIMONY COMPOUNDS

### Defects

**093451 ANTISITE DEFECTS IN  $\text{Sb}_{2-x}\text{Bi}_x\text{Te}_3$  MIXED CRYSTALS.** In layered mixed crystals of  $\text{Sb}_{2-x}\text{Bi}_x\text{Te}_3$  two types of point defect are considered: the antisite defects  $\text{Bi}_{\text{Te}}$  and  $\text{Sb}_{\text{Te}}$ . Using previously determined free carrier concentrations in the mixed crystals and the results of quantum chemical calculations, a model has been proposed which enables one to determine the energy of formation of the antisite defects and their concentrations for various values of  $x$ . The results show that the  $\text{Sb}_{\text{Te}}$ -defect concentration decreases monotonically with increasing content of Bi atoms in the whole region  $0 < x < 2$ , while the  $\text{Bi}_{\text{Te}}$ -defect concentration goes through a maximum at  $x=0.5$ . Changes in the structural parameters are also explained in terms of the quantum chemical calculations. (Author abstract) 14 refs.

Stary, Z. (Univ of Chemical Technology, Pardubice, Czech); Horak, J.; Stordeur, M.; Stoelzer, M. *J Phys Chem Solids* v 49 n 1 1988 p 29-34.

**093452 ANTISITE DEFECTS IN  $\text{Sb}_{2-x}\text{In}_x\text{Te}_3$  MIXED CRYSTALS.** Changes in the values of the plasma resonance frequency and some transport coefficients (electrical conductivity, Hall coefficient, Seebeck coefficient) of  $\text{Sb}_{2-x}\text{In}_x\text{Te}_3$  crystal show that an increase in the content of incorporated In atoms causes a decrease in the free carrier concentration. This result is interpreted in the following way. In atoms are incorporated in the Sb-sublattice and form uncharged substitutional defects  $\text{In}_{\text{Sb}}$  which, of the higher electropositivity of In than Sb, cause an increase in bond polarity and also in crystal ionicity. This effect leads to an increase in the energy of formation of antisite defects, such that the concentration of antisite defects is decreased with increasing values of  $x$ . (Edited author abstract) 17 refs.

Horak, J. (Technical Univ of Chemical Engineering, Pardubice, Czech); Stary, Z.; Lostak, P.; Pancir, J. *J Phys Chem Solids* v 49 n 2 1988 p 191-198.

## Doping

**093453 EFFECT OF SELENIUM OF THE ELECTRIC PROPERTIES OF  $\text{Sb}_2\text{Te}_3$ .** During the doping of antimony telluride single crystals with selenium the electric conductivity decreases with an increase in the impurity concentration. This is probably related to compensation of the antimony positive charge upon introduction of the impurities and to defects in the structure of the compound itself. In Russian. 5 refs.

## Low Temperature Properties

**093454 ELECTRICAL CONDUCTIVITY STUDY OF AN  $\text{SbSi}$  INGOT AT LOW TEMPERATURE.** A study of the temperature dependence of the electrical conductivity in the low-temperature region is made on a  $\text{SbSi}$  ingot for the first time. The ingot used in the present investigation is grown from melt by the temperature-fluctuation technique. The electrical conductivity is measured by applying a weak dc field along the c axis (needle axis) of the crystals. An anomaly is observed at 225 K in the plot of the electrical conductivity against temperature of the sample. This second-order phase-transition temperature obtained from the electrical conductivity study made on the  $\text{SbSi}$  ingot is compared with that obtained from other studies made on individual single-crystalline needles as well as inter-growths grown by other techniques and the results are discussed. (Author abstract) 10 refs.

## Magnetic Properties

**093455 FURTHER INVESTIGATIONS ON THE TEMPERATURE-DEPENDENCE OF MAGNETIC SUSCEPTIBILITY AND THERMOGRAVIMETRY OF STOICHIOMETRIC ANTIMONY TRISELENIDE AND ANTIMONY TRITELLURIDE SEMICONDUCTORS.** Stoichiometrically adjusted antimony triselenide and antimony tritelluride semiconductors were carefully prepared for the first time. Numerous measurements were carried out, involving X-ray diffraction analysis, true density, thermogravimetric analysis and the temperature-dependence of the magnetic susceptibility. The results obtained indicated that antimony triselenide and antimony tritelluride polycrystals possess mass susceptibilities of  $-0.361 \times 10^{-6}$  and  $-0.386 \times 10^{-6}$  C.G.S., respectively. The results are discussed on the basis of electronegativity difference, partial ionicity of the bond, and bond strength. (Author abstract). 15 Refs.

Abou-Sekina, M.M. (Tanta Univ, Tanta, Egypt). *J Therm Anal* v 34 n 1 Jan-Feb 1988 p 155-159.

## Photoconductivity

**093456 STUDY OF LOCALIZED STATES IN AMORPHOUS CHALCOGENIDE  $\text{Sb}_2\text{S}_3$  FILMS.** Thin films of  $\alpha\text{-Sb}_2\text{S}_3$  were prepared by thermal evaporation. Experimental parameters usually related to electronic disorder were studied, such as the exponent of the photoconductivity and the optical absorption edge. The results suggest that the defects in this material induce a density of state with exponential band tails. (Author abstract) 20 refs.

Droichi, M.S. (Univ de Sao Paulo, Sao Paulo, Brazil); Vaillant, F.; Bustarret, E.; Jousse, D. *J Non Cryst Solids* v 101 n 2-3 May 1988 p 151-155.

## Physical Properties

**093457 CONCENTRATION DEPENDENCES OF THE PROPERTIES OF  $\text{SnTe}$ -BASED SOLID SOLUTIONS OF THE  $\text{Sn-Sb-Te}$  SYSTEM.** In  $\text{SnTe}$ -based solid solutions of the  $\text{Sn-Sb-Te}$  system the dependences of the microhardness, the Hall carrier concentration and the thermoelectric power on the Te content along the Sb

isoconcentrate were found to be of nonmonotonic nature. The results obtained are interpreted on the basis of concepts concerning a chemical reaction in the solid solution leading to the formation of  $\text{Sb}_2\text{Te}_3$  molecular complexes. In Russian.

## Spectroscopic Analysis

**093458 X-RAY SPECTROSCOPIC AND THEORETICAL INVESTIGATION OF THE ENERGY BAND STRUCTURE OF  $\text{SbSi}$ .**  $\text{SbSi}$  is a representative of a very interesting class of compounds having both ferroelectric and semiconducting properties. A complex experimental and theoretical investigation of the energy band structure of  $\text{SbSi}$  is reported. Unlike earlier experiments, the X-ray spectroscopic method, which allows the distribution of the local partial density of states (DOS) in a broad energy interval is used. 17 refs.

## Switching

**093459 NONLINEAR I-V BEHAVIOUR & THRESHOLD SWITCHING IN DISORDERED  $\text{Sb-Se-Te}$  SYSTEM.** The nonlinear I-V behavior and threshold switching of bulk disordered  $\text{Sb}_2\text{Se}_3$  Te system have been experimentally studied. It is seen that above a certain voltage, the current through the material shoots to a very high value whereas the potential across the material drops to a very low value. The first virgin switching was observed at 98 V and stable reproducible switching at 205 V. An attempt is made to explain the nonlinear I-V behavior and the threshold switching using the charged defect states existing in the bulk material. The variation of switching voltage with number of switching cycles is also satisfactorily explained using the concept of filament formation and formation of insulating layer in between the electrode and the sample. (Author abstract) 17 refs.

Muragi, B.D. (Shivaji Univ, Kolhapur, India); Zope, J.K. *Indian J Pure Appl Phys* v 25 n 2 Feb 1987 p 77-79.

## Thin Films

**093460 ELECTRICAL CONDUCTIVITY AND THERMOELECTRIC POWER OF AMORPHOUS  $\text{Sb}_2\text{Te}_3$  THIN FILMS AND AMORPHOUS-CRYSTALLINE TRANSITION.** The results of electrical conductivity and thermoelectric studies on antimony telluride, a promising thermoelectric material, in the thin film state are reported. Films were vacuum-deposited on to clean glass substrates with thickness between 50 and 200 nm and studied in the temperature interval 300 to 470 K. On heating the as-grown films, there is a sharp fall both in the Seebeck coefficient and the electrical resistivity at around 340 to 370 K for all the films. This is attributed to an amorphous to crystalline transition, which is confirmed by X-ray diffractogram and electron diffraction patterns. (Author abstract) 9 refs.

Damodara Das, V. (Indian Inst of Technology, Madras, India); Soundararajan, N.; Pattabi, Manjunatha. *J Mater Sci* v 22 n 10 Oct 1987 p 3522-3528.

**093461 ON THE STRUCTURE AND TRANSFORMATION OF THE ORANGE FORM OF  $\text{Sb}_2\text{S}_3$  LAYERS.** In the present work we present structural studies concerning the orange modification of semiconducting antimony trisulfide. The behavior of the electrical conductivity of thin vacuum-deposited films with temperature in the range from 25 to 190°C is also considered. X-ray diffraction study showed that the orange modification of antimony trisulfide can neither be considered as amor-

phous material nor does it change into the black modification upon grinding. Thin vacuum-deposited layers, prepared by conventional thermal evaporation of the bulk material in  $5 \times 10^{-6}$  torr on an amorphous substrate at room temperature, were crystalline. The behavior of the electrical conductivity with temperature in the range 25 to 190°C indicated transition points at 80, 108, 135 and 175°C. (Edited author abstract) 18 refs.

## Transport Properties

**093462 ELECTRICAL TRANSPORT PROPERTIES OF AMORPHOUS SEMICONDUCTING  $\text{Sb-Se-Te}$  SYSTEM.** Dc conductivity and thermoelectric power (TEP) studies of  $\text{Sb}_2\text{Se}_3\text{Te}$  system have been experimentally investigated. The linear relationship between thermo e.m.f. and temperature difference and p-type nature of the material have been explained on the basis of charged defect states and unsymmetric broadening of mobility edges. (Author abstract) 4 refs.

Muragi, B.D. (Shivaji Univ, Kolhapur, India); Zope, J.K. *Key Eng Mater* v 13 pt 2 1987, Int Conf on Met and Semicond Glasses (MSG-86), Hyderabad, India, Dec 16-20 1986 p 509-513.

## SEMICONDUCTING BISMUTH COMPOUNDS

**093463 BISMUTH VALENCE ORDER-DISORDER STUDY IN  $\text{BaBiO}_3$  BY POWDER NEUTRON DIFFRACTION.** Two structural arrangements have been shown to exist for the perovskite-like compound  $\text{BaBiO}_{3.5}^{3+} \text{BiO}_{5.5}^{5+} \text{O}_3$  by powder neutron diffraction data. The first is characterized by a partial (75%) order of the  $\text{Bi}^{3+}$  and  $\text{Bi}^{5+}$  cations on the two crystallographically independent sites, while in the second arrangement the two cations are almost 100% disordered. The structure of eleven differently-prepared  $\text{BaBiO}_3$  samples showed that the deciding factor for obtaining one or the other arrangement is the temperature at which the sample is prepared or subsequently heat-treated. On the contrary, the cooling rate and the atmosphere (air or oxygen) do not seem to be important parameters. DTA measurements indicated that  $\text{BaBiO}_3$  undergoes an additional phase transition at 860°C on heating and 801°C on cooling. (Edited author abstract) 13 refs.

Chailout, C. (NBS, Gaithersburg, MD, USA); Santoro, A.; Remeika, J.P.; Cooper, A.S.; Espinosa, G.P.; Marezio, M. *Solid State Commun* v 65 n 11 Mar 1988 p 1363-1369.

## Doping

**093464 EFFECT OF A MAGNETIC FIELD ON THE THERMOELECTRIC PROPERTIES OF TIN-DOPED SOLID SOLUTIONS OF ANTIMONY (9 AT.%) IN BISMUTH.** In Tin-doped alloys of bismuth with 9 at.% antimony the effect of a magnetic field on the electric resistivity, thermoelectric power and thermal conductivity remains qualitatively the same as in the undoped alloy. However, the increase in the resistivity and thermoelectric power is intensified, and the effect of the magnetic field on the thermal conductivity is attenuated. Therefore no significant increase in the thermoelectric and magnetothermoelectric Q-factor occurs. In Russian. 8 refs.

Zemskov, V.S.; Belaya, A.D.; Zayakin, S.A.; Bulatova, N.A. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 4 Apr 1987 p 554-557.

**093465 BEHAVIOR OF Te IN PLASTICALLY DEFORMED  $\text{Bi}_2(\text{Te, Se})_3$  ALLOYS.** Plastic deformation of alloys based on  $\text{Bi}_2(\text{Te, Se})_3$  leads to the dissolution of the Te present in the second phase with an increase in pressure. Deformation and temperature accelerate the

dissolution. Primary recrystallization caused by a high degree of deformation decreases the solubility of Te in newly forming crystalline grains. 6 refs. In Russian.

Erofeev, R.S.; Scherbina, E.I. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 6 Jun 1987 p 907-911.

**093466 MONOCRYSTALLINE STRUCTURE OF  $\text{Bi}_2\text{Te}_3\text{-Bi}_2\text{Se}_3$  WITH A p-n JUNCTION.** We describe the preparation of the  $\text{Bi}_2\text{Te}_3\text{-Bi}_2\text{Te}_{3-x}\text{Se}_x$  monocrystalline structure with a selenium concentration gradient and a p-n junction. The formation of this structure and the decrease in free-hole concentration are explained on the basis of the interaction of incorporated selenium atoms with the antistructural defects of the  $\text{Bi}_2\text{Te}_3$  lattice. Samples with a selenium concentration gradient were prepared from the p- $\text{Bi}_2\text{Te}_3$  single crystal. Evidence of the formation of a p-n junction was obtained from current-voltage characteristics of the  $\text{Bi}_2\text{Te}_3\text{-Bi}_2\text{Te}_{3-x}\text{Se}_x$  monocrystalline structure. 14 refs.

Lostak, P. (Inst of Chemical Technology Pardubice, Czech); Horak, J.; Novotny, R.; Kliorka, J. *J Mater Sci Lett* v 6 n 12 Dec 1987 p 1469-1470.

**093467 OPTICAL PROPERTIES OF GALLIUM-DOPED  $\text{Bi}_2\text{Te}_3$  SINGLE CRYSTAL.** Reflectance and transmittance in the infrared spectral region were determined on Ga-doped  $\text{Bi}_2\text{Te}_3$  single crystal samples grown using a modified Bridgman technique the type of electrical conductivity is found from the polarity of thermopower. The plasma resonance frequency, optical relaxation time, and high-frequency dielectric constant were determined by fitting the Drude-Zener formulas to the reflectance spectra. Ga impurities act as donors. This effect is qualitatively explained by interaction of substitutional defects with anti-site defects and by the formation of interstitial ions. The dependence of the absorption coefficient on the energy of incident photons is discussed. (Edited author abstract). 15 refs.

Lostak, P. (Czechoslovak Acad of Sciences, Pardubice, Czech); Novotny, R.; Navratil, J.; Sramkova, J. *Phys Status Solidi A* v 106 n 2 Apr 1988 p 619-625.

## Electric Conductivity

**093468 ELECTROOPTIC MEASUREMENT OF THE VOLUME RESISTIVITY OF BISMUTH SILICON OXIDE ( $\text{Bi}_{12}\text{SiO}_{20}$ ).** Single crystals of bismuth silicon oxide ( $\text{Bi}_{12}\text{SiO}_{20}$ ) and its isomorphs (including, for example, bismuth germanium oxide ( $\text{Bi}_{12}\text{GeO}_{20}$ )) have been utilized in a wide range of active electrooptic and acousto-optic devices. A key material parameter that influences device performance characteristics is the volume resistivity, which is difficult to measure accurately using standard techniques in refractory oxides like  $\text{Bi}_{12}\text{SiO}_{20}$  due to its large magnitude (typically  $> 10^{13} \Omega \text{ cm}$ ). We present here a technique for the measurement of such very high resistivities in electrooptic materials; this method utilizes the electrooptic modulation induced by a voltage placed across the (crystallographically oriented) sample as a probe of temporal voltage transients that are in turn directly related to the sample volume resistivity. The technique is described in detail, and experimental results are presented on a number of undoped and doped samples of bismuth silicon oxide grown by the Czochralski technique. (Edited author abstract) 17 refs.

Seery, David A. (Univ of Southern California, Los Angeles, CA, USA); Garrett, Mark H.; Tanguay, Armand R. *J Cryst Growth* v 85 n 1-2 Nov 1 1987, Amer Cryst Growth 1987, Proc of the Seventh Amer Conf on Cryst Growth, Monterey, CA, USA, Jul 12-17 1987 p 282-289.

## Electric Properties

**093469 THERMOELECTRIC PROPERTIES OF  $\text{Bi}_{1-x}\text{Sb}_x$  FILMS WITH  $0 < x \leq 0.3$ .** The electrical conductivity, its temperature coefficient and the thermoelectric power of  $\text{Bi}_{1-x}\text{Sb}_x$  films with  $0 < x \leq 0.3$  and thicknesses from 20 to 400 nm were measured in the temperature range 80-400 K. The results are discussed in the framework of a previously proposed anisotropic

non-degenerate two-band model. (Author abstract) 31 refs.

Voelklein, F. (Akad der Wissenschaften der DDR, Jena, East Ger); Kessler, E. *Thin Solid Films* v 155 n 2 Dec 30 1987 p 197-208.

**093470 STRUCTURAL AND ELECTRICAL PROPERTIES OF BISMUTH TELLURIDE FILMS GROWN BY THE MOLECULAR BEAM TECHNIQUE.** Films of  $\text{Bi}_2\text{Te}_3$  were grown by coevaporation of its component elements. Direct evaporation of  $\text{Bi}_2\text{Te}_3$  was not suitable; it is noncongruent and results in a lack of stoichiometry. Molecular beams of bismuth and tellurium from effusion cells were condensed on silica substrates. The authors studied the composition and crystallographic properties of the films as a function of substrate temperature. They also investigated the thermoelectric properties, carrier concentration, mobility, and thermoelectric power. 7 refs.

Charles, E. (Univ des Sciences et Techniques du Languedoc, Montpellier, Fr); Groubert, E.; Boyer, A. *J Mater Sci Lett* v 7 n 6 Jun 1988 p 575-577.

## Optical Properties

**093471 EXCITONIC ABSORPTION AND URBACH'S TAIL IN BISMUTH SULFIDE SINGLE CRYSTALS.** The absorption coefficient of bismuth trisulfide single crystals has been measured through more than four orders of magnitude and in the range of energies from 1.25 to 1.70 eV. A detailed study as a function of temperature has been carried out from 29 to 300 K. An Urbach tail for low values of absorption has been found. This tail and its temperature evolution fit the expression for ionic materials. An excitonic region appears at low temperature and the shape of the exciton peak is Gaussian, which corresponds to a strong exciton-phonon coupling. The exciton binding energy is estimated ( $28 \pm 3 \text{ meV}$ ) and then the energy gap at 29 K is obtained ( $E_g = 1.523 \pm 0.003 \text{ eV}$ ). The fundamental electronic transition has been found to be a strongly anisotropic allowed direct transition. From reflectivity measurements a localized level at 1.361 eV at 29 K has been found. The change of the gap with temperature is interpreted through an electron-phonon mechanism. (Author abstract) 46 refs.

Cantarero, A. (Univ de Valencia, Valencia, Spain); Martinez-Pastor, J.; Segura, A.; Chevy, A. *Appl Phys A* v 45 n 2 Feb 1988 p 125-132.

## Phase Equilibria

**093472 VAPOUR-SOLID PHASE EQUILIBRIUM OF  $\text{Bi}_2(\text{Se}_{1-x}\text{S}_x)_3$  TERNARY CRYSTALS.** With the objective of analyzing the relations between the concentration of free carriers in  $\text{Bi}_2(\text{Se}_{1-x}\text{S}_x)_3$  ternary crystals and the vapour pressures of selenium and/or sulfur, a model describing the equilibrium between the vapour and the solid phase of a ternary crystal has been worked out by adopting the simplification that the ternary system can be taken for an ideal solid solution where the activity of  $\text{Bi}_2\text{S}_3$  is equal to its concentration. The proposed model explains well the experimentally observed variation of the concentration of free carriers in  $\text{Bi}_2(\text{Se}_{1-x}\text{S}_x)_3$  crystals with increasing value of  $x$  ( $x = 0.00-0.16$ ) under identical growth conditions. (Edited author abstract) 10 refs.

Horak, J. (Technical Univ of Chemical Engineering, Pardubice, Czech); Novotny, R.; Lostak, P.; Hoschl, P. *J Phys Chem Solids* v 48 n 12 1987 p 1227-1233.

**093473 STUDY OF HETEROGENEOUS EQUILIBRIA IN THE  $\text{BiBr}_3\text{-Bi}_2\text{Se}_3$  SYSTEM.** The p-T-x phase diagram of the  $\text{BiBr}_3\text{-Bi}_2\text{Se}_3$  system was constructed using differential thermal and x-ray phase analyses and by tensimetric vapor pressure determination. Two crystalline compounds,  $\text{BiSeBr}$  and  $\text{Bi}_2\text{Se}_3\text{Br}$ , melting incongruently at  $783 \pm 5$  and  $843 \pm 5 \text{ K}$ , respectively, and a small range of solid solutions on the bismuth selenide side are noted in this system. On the basis of the data obtained, the enthalpy and entropy variations for dissociative evaporation of the compounds are calculated, and

estimates are made of the standard thermodynamic characteristics of crystalline bismuth selenobromides. 12 refs. In Russian.

Vorob'eva, T.A.; Kolomnina, E.V.; Trifonov, V.A.; Popovkin, B.A.; Novoselova, A.V. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 11 Nov 1987 p 1843-1846.

## Phase Transitions

**093474 MAGNETIC FREEZE-OUT AND MAGNETIC-FIELD-INDUCED SEMICONDUCTOR-SEMIMETAL TRANSITION IN  $\text{Bi}_{1-x}\text{Sb}_x$  ALLOYS UNDER HIGH HYDROSTATIC PRESSURE.** The galvanomagnetic properties of extremely pure single-crystal  $\text{Bi}_{1-x}\text{Sb}_x$  alloys ( $x \approx 0.07$  to  $0.08$ ) are investigated under hydrostatic pressure with static magnetic fields in the range 0 to 6 T. A striking anomalous behaviour of the longitudinal magnetoresistance is observed in pure crystals as the magnetic field is increased above a certain critical value. At low magnetic fields and at high magnetic fields the electrical resistivity increases with increasing temperature in a metallic manner in contrast to the thermally activated behaviour observed at intermediate fields. A strong enhancement of the observed anomalies under hydrostatic pressure is found. The anomalous properties are associated with charge carrier freeze-out effect in the intermediate field regime and a magnetic-field-induced semiconductor-semimetal transition in high magnetic fields. (Edited author abstract). 33 refs.

Kraak, W. (Humboldt-Univ zu Berlin, Berlin, East Ger); Troppenz, U.; Herrmann, R.; Chudinov, S.M.; Kulbachinskii, V.A. *Phys Status Solidi B* v 148 n 1 Jul 1988 p 333-347.

## Spectroscopic Analysis

**093475 VOLUME AND QUASI-SURFACE EXCITONIC STATES IN LAYERED SEMICONDUCTOR.** The influence of the surface states and the intensity of the laser emission with the quantum energy  $\hbar\nu > E_g$  on the reflectance and the photoluminescence spectra of  $\text{Bi}_2\text{S}_3$  single crystals in temperature range of 4.2-77 K are studied. The quasi-surface excitons, theoretically predicted previously, were obtained experimentally. (Author abstract) 3 refs.

Lisitsa, M.P. (Acad of Sciences of the Ukrainian SSR, Kiev, USSR); Motsny, F.V. *J Lumin* v 40-41 Feb 1988, Excited State Processes in Condensed Matter, Proc of the Int Conf on Lumin, Beijing, China, Aug 17-21 1987 p 497-498.

## Thermoelectric Effects

**093476 THERMOELECTRIC PROPERTIES OF LEAD-DOPED SINGLE CRYSTALS OF SOLID SOLUTIONS OF THE  $\text{Sb}_{1.5}\text{Bi}_{0.5}\text{Te}_3\text{-Bi}_2\text{Se}_3$  SYSTEM.** A study was made of the temperature dependences of the thermoelectric power and the electric conductivity of lead-doped single crystals of solid solutions of the  $\text{Sb}_{1.5}\text{Bi}_{0.5}\text{Te}_3\text{-Bi}_2\text{Se}_3$  system in the 100-300 K range. It is shown that doping with lead has no effect on the nature of these dependences, the slopes of which are determined mainly by the degree of deviation of the solid-solution composition from the stoichiometric. 7 refs. In Russian.

## Thin Films

**093477 DEPOSITION OF CHALCOGENIDE THIN FILMS BY SOLUTION GROWTH TECHNIQUE ON POLYMER SURFACES.** This letter describes the deposition of thin films of chalcogenides on polymer substrates. Thermal treatment of polymer substrates is needed because of the presence of mechanical strains during its sheet formation by a mechanical process. Non-uniform mechanical strain causes inhomogeneous oxidation of the surface which results in a non-uniform deposition of chalcogenides thin films. 12 refs.

## Activation

**093478 ELECTRICAL ACTIVATION OF LOW-FLUENCE BORON IMPLANTATION IN SILICON STUDIED BY PCV IN COMBINATION WITH SIMS.** The thermally induced electrical activation of boron implanted in silicon at fluences  $\leq 10^{13} \text{ cm}^{-2}$  was studied by the combination of secondary ion mass spectroscopy (SIMS) and pulsed capacitance voltage (PCV). After annealing at 900°C for 30 min boron is completely ionized and the contribution of electrically active defects to the electrical profile is negligible. For partly annealed samples ( $T < 900^\circ\text{C}$ ) the degree of electrical activation of boron decreases with increasing boron concentration due to the presence of residual defects. The experimental data can be described qualitatively by the first-order kinetics if the influence of residual crystal defects on the electrical activation is considered. (Author abstract) 26 refs.

## Applications See SEMICONDUCTING SILICON—Ion Implantation.

## Doping

**093479 CRYSTAL STRUCTURE OF THE PHASE  $\text{ZnB}_{0.25}$ .** On the basis of single-crystal diffractometry, a study is made of the structure of a solid solution of zinc in  $\beta$ -rhombohedral boron, and the coordinates of the  $\beta$  and Zn atoms are determined. An analysis is made of all the interatomic distances and the coordination polyhedra of the Zn atoms. A comparison is made of the structures of interstitial solid solutions of third-period transition-metal atoms in  $\beta$ -rhombohedral boron. In Russian. 8 refs.

## Laser Applications

**093480 STRUCTURE OF BORON FILMS PRODUCED BY LASER CHEMICAL REACTIONS IN THE FIELD OF THE PULSED  $\text{CO}_2$  LASER.** The method of high-resolution electron microscopy was used to examine the structure and constitution of boron films produced by laser-chemical reactions in the field of a pulsed  $\text{CO}_2$  laser. The results show that the film represents the statistically distributed structural elements, i.e., clusters of boron atoms with the icosahedral structure. It was also shown that the initial amorphous structure of boron transforms in laser heating into the  $\beta$ -rhombohedral crystal structure with the crystallographic parameters typical of  $\beta$ -boron. (Author abstract) 5 refs.

**093482 ELECTROCHEMICAL AND ELECTRO-OPTICAL STUDY OF THE STRAINED-LAYER SUPERLATTICE SYSTEM:  $\text{CdTe-ZnTe}$ .** The behavior of  $\text{CdTe-ZnTe}$  strained-layer superlattices has been investigated for the first time in electrolytic medium. The role of the electrochemical control of the superlattice/electrolyte interface is emphasized for gaining information on the material using the electrochemical technique. Measurements in the dark and under illumination enable avoiding spurious electrochemical reactions in further investigations, and the p-type conductivity of these superlattices is determined unambiguously. Photocurrent spectroscopy and electroreflectance measurements in electrolytic medium are coupled in order to determine the various transition energies of these complex structures. (Edited author abstract) 30 refs.

**093483 PHOTOCHEMISTRY OF COLLOIDAL SEMICONDUCTORS. 25. QUENCHING OF  $\text{CdS}$  FLUORESCENCE BY EXCESS POSITIVE HOLES.** Colloidal  $\text{CdS}$  dissolves anodically (to yield  $\text{Cd}^{2+}$ ,  $\text{SO}_3^{2-}$ , and  $\text{SO}_4^{2-}$  ions) when it is attacked by OH radicals produced by  $\gamma$ -irradiation. The fluorescence intensity of  $\text{CdS}$  slightly decreases during the first stages of this dissolution, but drastically increases in the later stages as the particles become very small. This increase is attributed to the removal of surface sites at which the radiationless recombination of charge carriers takes place. It is shown that the longer the lifetime of fluorescence the more efficient is the quenching. The holes injected by OH radicals slowly leave the particles which then become fluorescent again. The consequences of this effect in photocatalysis are pointed out. A mechanism of quenching is discussed. (Edited author abstract) 15 refs.

**093486 PHOTOCHEMISTRY OF COLLOIDAL SEMICONDUCTORS. 26. PHOTOELECTRON EMISSION FROM  $\text{CdS}$  PARTICLE AND RELATED CHEMICAL EFFECTS.** Laser illumination of small  $\text{CdS}$  particles in aqueous solution leads to the formation of hydrated electrons, which are detected by their strong absorption. The yield increases with decreasing particle size. The maximum quantum yield observed is 0.07 electrons emitted per photon adsorbed. At the highest laser intensities applied, five electrons are emitted from one colloidal particle. The absorption of the remaining holes is also observed. The emitted electrons react with colloidal particles in solution. During the laser flash a strong bleaching signal, attributed to the electrons generated in the particles, is recorded shortly below the onset of absorption. With knowledge of the specific absorbance, the stationary concentration of electrons on the particles during the laser flash is calculated. These effects are studied at various laser intensities. (Edited author abstract) 16 refs.

## Charge Carriers See Also MAGNETIC SEMICONDUCTORS—Physical Properties.

**093489 ACOUSTOELECTRIC MEASUREMENTS OF MINORITY AND MAJORITY CARRIER MOBILITIES IN SEMICONDUCTORS INCLUDING  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ .** Acoustoelectric voltages versus absorbed surface acoustic wave (SAW) power measurements are

used to nondestructively determine carrier mobilities in bulk silicon, GaAs and epitaxial  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  employing a separate medium convolver structure. The longitudinal component of the acoustoelectric signals (LAV) has been used in the past to determine the carrier mobilities in semiconductor films. In the present work, it is shown that the transverse component of the acoustoelectric signals (TAV) can also be used to measure the carrier mobilities. TAV and LAV measurements yield mobilities in perpendicular directions. Hence, these measurements can be used to study the electron mobilities of a two-dimensional electron system in superlattices. A new delay line structure is introduced to invert the semiconductor surface through the field effect to measure the minority carrier mobilities. Carrier mobilities in graded epitaxial  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  are measured after subsequent etching of the surface to obtain the mobility values versus depth. The findings of the above measurements and Hall measurements are in satisfactory agreement. (Author abstract) 16 refs.

**093490 OBSERVATION OF CYCLOTRON RESONANCE IN CdSe BELOW THE METAL-INSULATOR TRANSITION.** We report the observation of electron cyclotron resonance (CR) in n-type CdSe with an average carrier density below the metal-insulator transition ( $N_d^{1/3}a^* = 0.08$ ). A plasma-shifted electron cyclotron resonance (SCR) is also observed. The number of carriers participating in cyclotron resonance, which is more than 4 orders less than  $N_d \cdot N_a$ , increases rapidly with magnetic field, in agreement with a previous calculation based on Poisson distribution of donors. This supports the picture of metallic donor clusters within doped semiconductors due to random distribution of impurities. The simultaneous appearance of both CR and SCR is interpreted in terms of the breakdown of the Maxwell Garnett theory for random-donor semiconductors. (Author abstract) 6 refs.

Lee, M.W. (Univ of Maryland, College Park, MD, USA); Drew, H.D. *Solid State Commun* v 62 n 12 Jun 1987 p 825-828.

**093491 CORRELATION BETWEEN CARRIER CONCENTRATION IN  $\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$ .** In order to use ( $\text{HgCd}$ )Te for photoconductive detector applications, material with a near-intrinsic free carrier concentration and therefore few residual impurities is required. Material with a high carrier concentration has been found to contain relatively large amounts of chlorine and there is a correlation between the Cl concentration and the carrier concentration determined using the Hall effect. The sources of Cl contamination have been found to be the Cd starting material, chemicals used to clean the starting materials as well as the silica ampules used during growth. (Author abstract) 8 refs.

Marais, M.A. (CSIR, Pretoria, S Afr); Strydom, H.J.; Basson, J.H.; Rogers, D.E.C.; Booyens, H. *J Cryst Growth* v 88 n 3 May 1988 p 391-396.

**093492 CARRIER RECOMBINATION IN  $\text{p-Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$  AND  $\text{n-Hg}_{0.7}\text{Cd}_{0.3}\text{Te}$ .** Transport and photoconductive properties of  $\text{p-Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$  and  $\text{n-Hg}_{0.7}\text{Cd}_{0.3}\text{Te}$  have been studied at temperatures between 16 and 250 K. The crystals showed different lifetimes than that observed in n-type  $\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$ , where Auger recombination was found as the dominating recombination mechanism. The minority carrier lifetime in  $\text{p-Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$  could be explained by Shockley-Read recombination involving a deep donor-like centre located about 6 meV above the valence band edge. In n-type  $\text{Hg}_{0.7}\text{Cd}_{0.3}\text{Te}$  radiative recombination was found to dominate at temperatures above 40 K. Obviously the band gap of this composition is too wide for an effective Auger mechanism. Below 40 K trapping of minority carriers occurs and one observes two life time constants. Here the recombination mechanism was identified as recombination via defects in the band gap. (Author abstract) 17 refs.

**Chemical Vapor Deposition** See Also SOLAR CELLS—Thin Films.

**093493 THERMODYNAMIC ANALYSIS OF THE GROWTH OF  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  BY MOCVD.** The dependence of the compositional parameter  $x$  in  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  (MCT) upon the growth temperature and feed compositions has been analyzed by thermodynamic principles. The results indicate that  $x$  increases sharply from its low temperature values to unity once the growth temperature has reached a critical point, where the decomposition of  $\text{HgTe}$  becomes significant. Higher Hg/Cd ratios, as well as higher DETe concentrations in the feed can help to prevent  $\text{HgTe}$  decomposition until higher temperatures are reached and are thus more desirable growth conditions for MCT using the MOCVD method. (Author abstract) 22 refs.

Liaw, Ing-Ruey (Nat'l Tsing Hua Univ, Hsinchu, Taiwan); Chou, Kan-Sen; Lin, Ming-Shyong. *J Cryst Growth* v 87 n 4 Mar 1988 p 529-534.

**093494 ENTHALPY CHANGE IN MOVPE PREPARATION OF MERCURY CADMIUM TELLURIDE.** Heat balance calculations for the preparation of mercury cadmium telluride by the interdiffused multilayer process from the gas phase by thermal decomposition of dimethyl cadmium,  $\text{Me}_2\text{Cd}$ , or Hg vapor with diethyl telluride,  $\text{Et}_2\text{Te}$ , show that the enthalpy change for the process is due mostly to the formation of hydrocarbons from the metal alkyls, rather than to the formation of CdTe or HgTe. (Author abstract) 10 refs.

McAllister, Trevor (CSIRO, Clayton, Aust). *J Cryst Growth* v 91 n 1-2 Aug 1988 p 218-220.

**093495 PHOTO-MOCVD GROWTH OF  $\text{HgTe}$ - $\text{CdTe}$  SUPERLATTICES.**  $\text{HgTe}$ - $\text{CdTe}$  superlattices have been grown by photo-assisted metalorganic chemical vapor deposition (MOCVD). The substrate temperatures used were 182°C and 240°C. Superlattices were obtained despite low growth rates requiring long growth times, up to 12 h. Superlattice structures were verified by cross-sectional transmission electron microscope (TEM) and diffractometer X-ray diffraction patterns. The X-ray diffraction patterns showed satellite peaks up to third order. A grid-like array of dislocations at the substrate layer interface, suggesting operation of a dislocation-blocking mechanism, was observed. The electrical properties of superlattices grown at higher temperature (240°C) were improved compared with those grown at lower temperature (182°C) and had n-type conductivity as grown, with carrier concentrations approximately  $10^{16} \text{ cm}^{-3}$  and mobilities approximately  $10^4 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ . Infrared transmission/reflection measurements showed that the superlattice absorption edge was shifted to longer wavelengths compared with the homogeneous alloy of the same CdTe fraction ( $x$ -value), as expected. (Author abstract) 21 refs.

Ahlgren, William L. (Santa Barbara Research Cent, Goleta, CA, USA); Smith, E.J.; James, J.B.; James, T.W.; Ruth, R.P.; Patten, E.A.; Knox, R.D.; Staudenmann, J.-L. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 198-209.

**093496 TEMPERATURE-INDEPENDENT UNASSISTED PYROLYTIC MOCVD GROWTH OF CADMIUM TELLURIDE AT 250°C USING 2,5-DIHYDROTELUROPHENE.** The molecule 2,5-dihydrotelurophene (DHTe) was identified, synthesized and tested to determine its potential as a Te source for unassisted pyrolytic MOCVD growth of  $\text{Hg}_x\text{Cd}_{1-x}\text{Te}$  at substrate temperatures  $\approx 300^\circ\text{C}$ . Experiments were concentrated on unassisted pyrolytic growth of CdTe using DHTe and dimethylcadmium (DMCd) as a Cd source. The long-term stability of DHTe far exceeded theoretical expectations. Cadmium telluride growth rates were a linear function of the DHTe flow rate and independent of substrate temper-

ature at or above 250°C. All CdTe layers grown on high-resistivity CdTe substrates were p-type, with carrier concentrations between  $6.2 \times 10^{15}$  and  $4.2 \times 10^{16} \text{ cm}^{-3}$ . The best electrical properties were obtained at a growth temperature of 250°C, where the p-type carrier concentration was  $6.2 \times 10^{15} \text{ cm}^{-3}$  and the Hall mobility was  $80 \text{ cm}^2/\text{V}\cdot\text{s}$ . (Edited author abstract) 17 refs.

Lichtmann, L.S. (Hughes Research Lab, Malibu, CA, USA); Parsons, J.D.; Cirlin, E.-H. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 217-221.

**093497 TEMPERATURE-INDEPENDENT UNASSISTED PYROLYTIC MOCVD GROWTH OF CADMIUM TELLURIDE AT 290°C AND MERCURY TELLURIDE AT 325°C USING DIMETHYLCADMIUM, METHYLALYLTELLURIDE AND DIMETHYLMERCURY.** Methylallyltelluride (MATE) was synthesized and tested as part of a joint effort between American Cyanamid Co. and Hughes Research Laboratories to develop a Te alkyl suitable for low-temperature, high-growth-rate epitaxy of  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  (MCT) alloys by unassisted pyrolytic metalorganic chemical vapor deposition (MOCVD). Cadmium telluride and HgTe growth studies using MATE were performed at substrate temperatures between 250 and 350°C. Reproducible temperature-dependent CdTe growth rates as high as  $30 \mu\text{m/h}$  were achieved at or above 290°C. The decomposition characteristics of the Hg source, dimethylmercury (DMHg), limited the minimum temperature for temperature-independent growth of HgTe to 325°C. Between 325 and 340°C the maximum HgTe growth rates were  $15 \mu\text{m/h}$ . Room-temperature Hall measurements were performed on CdTe epitaxial layers grown on high-resistivity CdTe substrates at 300°C. These layers were p-type. (Edited author abstract) 15 refs.

Parsons, J.D. (Hughes Research Lab, Malibu, CA, USA); Lichtmann, L.S. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 222-227.

**093498 GROWTH OF  $\text{CdHgTe}$  BY MOCVD AT REDUCED TEMPERATURES.**  $\text{CdHgTe}$  has been grown by MOCVD at 350°C using IMP. The material was superior to that grown at 410°C in terms of surface morphology, decreased acceptor concentration and better interface control. The compositional uniformity was also greatly improved, and at 1% in  $x$  over  $1 \text{ cm}^2$  is the best ever reported for MOCVD grown CMT. (Author abstract) 19 refs.

Thompson, J. (GEC Research Ltd, Wembley, Engl); Mackett, P.; Smith, L.M.; Cole-Hamilton, D.J.; Shenai-Khatkate, D.V. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 233-239.

**093499 GROWTH OF  $\text{CdHgTe}$  BY METALORGANIC CHEMICAL VAPOUR DEPOSITION FOR OPTICAL COMMUNICATION DEVICES.** MOCVD has been used for the first time to grow  $\text{CdHgTe}$  by the interdiffused multilayer process for  $1.3\text{-}1.55 \mu\text{m}$  photodiodes. The growth has been optimised to give uniform material with a smooth surface morphology. The use of a HgTe layer as the p-type ohmic contact has resulted in photodiodes having a very low series resistance (30-35  $\Omega$ ). The epitaxial diodes have also exhibited good thermal stability. Other parameters are comparable with those obtained for bulk grown devices. (Author abstract) 11 refs.

## Compaction

**093500 HOT ISOSTATIC PRESSING OF CADMIUM SULPHIDE.** Cadmium sulfide, CdS, has some potential applications as a semiconductor. For example, it has been widely used in solar batteries, photometers (exposure meters) and so on. However, cadmium sulfide is a thermally unstable material which cannot be fully densified by normal sintering, because its sintering temperature is limited to a relatively low temperature. Pressure sintering is a promising technique because a reduction of sintering temperature and also simultaneous use of the capsule is favorable in the case of volatile materials. Hot isostatic pressing is a type of pressure sintering. The present letter is concerned with fabrication of dense bodies of cadmium sulfide. 7 refs.

**Computation** See SEMICONDUCTING ZINC COMPOUNDS—Computation.

## Contacts

**093501 TUNNELING EFFECT ON THE METAL-CdTe CONTACT.** A theoretical analysis is made of metal/CdTe contacts by a numerical method. Factors which influence the current density and contact resistance of the M-S junction are discussed. Besides the thermionic current component, the tunneling current, treated with the WKB approximation, is incorporated into the current transport across the M-S junction. It is shown that the latter should not be neglected, especially in cases of high doping concentration and low temperature. A set of optimum process parameters for contact of CdTe related devices is proposed. (Edited author abstract) 10 refs.

## Crystalline

**093502 PHOTOLUMINESCENCE OF CdTe CRYSTALS DOPED WITH OXYGEN AND ITS COMPARISON WITH ZnTe:O.** Photoluminescence spectra of CdTe crystals doped with oxygen at low temperature (4.9-20K) are investigated and a new emission peak O and its LO phonon replicas are observed. The energy positions of these peaks do not shift with the temperature and the excitation power. The emission peak O has been identified as the recombination of the exciton bound to oxygen center. The characteristic of luminescence from the  $O_{Te}$ -bound exciton in CdTe:O is compared with that in ZnTe:O. (Author abstract) 21 refs.

**Defects** See Also SEMICONDUCTING TELLURIUM COMPOUNDS—Defects.

**093503 PHOTOPYROELECTRIC SPECTROSCOPY (P<sup>2</sup>ES) OF ELECTRONIC DEFECT CENTERS IN CRYSTALLINE n-CdS.** Photopyroelectric spectroscopy (P<sup>2</sup>ES) of n-CdS single crystals was performed at an open circuit, and in conjunction with photocurrent spectroscopy (PCS) in the presence of an applied ac or dc transverse field. The results showed that P<sup>2</sup>ES is very sensitive to the presence of deliberately introduced subbandgap defect structures, with the P<sup>2</sup>E signal dominated by non-radiative de-excitation mechanisms at defect centers. The potential of this technique as a powerful electronic defect diagnostic tool, combined with the overall experimental simplicity, was demonstrated with mm-thick crystals used as received in an open-cell geometry. (Author abstract) 26 refs.

Mandelis, A. (Univ of Toronto, Toronto, Ont, Can); Loe,

W.; Wagner, R.E. *Appl Phys A* v A44 n 2 Oct 1987 p 123-130.

**093504 ELECTRON TRAPS IN SINGLE-CRYSTALL CdS.** Deep-level transient spectroscopy (DLTS) has been used to characterize bulk defect states in single-crystal boules of CdS grown from the vapor phase. Two centers are present in as-grown material with activation energies of 0.29 eV and 0.44 eV. However, annealing the crystals in either Cd or S appears to introduce two additional levels with activation energies of 0.61 eV and 0.74 eV. If the sample is maintained in the dark for some time, the DLTS peak disappears but can be recovered again by exposure to light. Apparently this cycle can be repeated indefinitely. Parallel observations in the scanning electron microscope have shown that the annealing process also produces a network of extended defects and subgrain boundaries. (Edited author abstract) 20 refs.

Claybourn, M. (Univ of Durham, Durham, Engl); Brinkman, A.W.; Russell, G.J.; Woods, J. *Philos Mag B* v 56 n 3 Sep 1987 p 385-395.

**093505 PHOTOCAPACITANCE STUDY OF DEFECTS IN PLASTICALLY-DEFORMED CdTe.** Deformation-induced defects have been investigated in both n- and p-type CdTe photocapacitance measurements (PCM). Two deep levels were observed in similar concentrations near the middle of the gap. The corresponding defects are supposed to be identical with those that have been found by other authors, using deep-level transient spectroscopy. From a fit of our data to models of the absorption cross-section we obtain the photo-ionization energies and can reliably estimate the activation enthalpies of the relaxed defect states, taking into account the electron-phonon interaction. The Huang-Rhys factor for the electron-phonon coupling of both states is of the order of twenty. (Author abstract) 14 refs.

**093506 DEEP LEVELS DUE TO DISLOCATIONS IN CdS.** Nonstationary capacitance spectroscopy (DLTS) is widely used in determining deep-level parameters for semiconductors. In application to dislocations, an important point in that the method in particular enables one to isolate the lines corresponding to extended defects. Also, the working volume is determined by the thickness of the depleted region in a Schottky diode and the contact area, so it can be extremely small, and therefore microindentation can be used to introduce dislocations, while one can also examine unevenly distributed growth dislocations. We have applied DLTS to cadmium sulfide and have identified signals in the spectra corresponding to certain dislocation types. 9 refs.

## Diffusion

**093510 INTERDIFFUSION IN MERCURY CADMIUM TELLURIDE EVALUATED FROM VAPOR PHASE GROWTH KINETICS.** A method is presented for determining interdiffusion coefficients from the kinetics of isothermal vapor phase epitaxial growth of mercury cadmium telluride ( $Hg_{1-x}Cd_xTe$ ). After an initial transient, growth is interdiffusion limited. Interdiffusion coefficients in the composition range  $x = 0.1$  to  $0.7$  and a temperature range of  $450$  to  $700^\circ C$  were determined using a simple geometric analysis of the composition profiles obtained in this interdiffusion limited regime. The technique offers advantages in simplicity and added control over the defect nature of the material during the interdiffusion process. The interdiffusion coefficients for the composition and temperature range studied are represented by the following equation:  $D_x (cm^2/s) = 300 \exp(-7.53x) \exp(-1.92 \text{ eV}/kT)$ . Comparison with other studies shows good agreement. (Author abstract) 19 refs.

**093511 SINTERING BEHAVIOUR AND ELECTRICAL PROPERTIES OF Cd<sub>1-x</sub>Zn<sub>x</sub>S FILMS CONTAINING CdCl<sub>2</sub>.** Polycrystalline Cd<sub>1-x</sub>Zn<sub>x</sub>S films were prepared by coating a slurry which consisted of CdS, CdCl<sub>2</sub>, various amounts of ZnS and propylene glycol on to glass substrates and by sintering in a nitrogen atmosphere, and their sintering behaviors and electrical properties were investigated. As the amount of ZnS increases, the enhancing effects of CdCl<sub>2</sub> on sintering and doping decrease, due primarily to the formation of ZnCl<sub>2</sub> which evaporates rapidly during sintering, resulting in poor microstructure and a sharp increase in electrical resistivity. The sharp increase in the electrical resistivity is related to a sharp decrease in electron concentration which is caused by poor doping efficiency, and by an increase in the donor ionization energy of chlorine as the zinc content increases. The trap density of grain boundaries, on the other hand, decreases with increasing zinc content in sintered Cd<sub>1-x</sub>Zn<sub>x</sub>S films. (Author abstract) 13 refs.

## Electric Properties

**093518 EFFECT OF AN ELECTRIC FIELD ON MASS TRANSFER OF SULFUR AND CADMIUM IN THIN POLYCRYSTALLINE CdS FILMS.** A study was made of the effect of an electric field in the electrophysical properties of thin cadmium sulfide films. It was found that the variation of the resistivity and photoconductivity of the films as a function of the coordinate is caused by accelerated ion displacement in the semiconductor layer above the surface and by the occurrence of quasi-chemical reactions leading to the formation of intrinsic defects in the bulk of the semiconductor. In Russian. 14 refs.

Ignatov, A.V. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 8 Aug 1987 p 1255-1257.

**093519 EFFECT OF COMPOSITIONAL INHOMOGENEITY ON THE ELECTRIC AND OPTICAL PROPERTIES OF Cd<sub>x</sub>Hg<sub>1-x</sub>Te SINGLE CRYSTALS ( $0.19 \leq x \leq 0.30$ ).** A study was made of the electric conductivity, the Hall effect and the Faraday effect on free charge carriers as a function of the geometrical dimensions of a Cd<sub>x</sub>Hg<sub>1-x</sub>Te sample with  $0.19 \leq x \leq 0.30$ . On the basis of this study, the electric parameters and the effective electron masses of this material were determined. The  $x$  distribution profile along the thickness of the sample and the amplitude of its fluctuations  $\Delta x$  were established experimentally. The possibility of a contactless method of determining compositional fluctuations in these crystals is shown. 9 refs. In Russian.

Abdinov, A.Sh.; Seidli, G.S.; Khydyrova, E.B.; Shukuyrov, N.M. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 11 Nov 1987 p 1835-1838.

**093520 DISLOCATIONS AND ELECTRICAL CHARACTERISTICS OF HgCdTe.** The electrical characteristics of HgCdTe samples have been experimentally examined as a function of dislocation density. MIS measurements on samples with a graded dislocation density ranging from about  $2 \times 10^5$  to  $2 \times 10^6$  cm<sup>-2</sup> showed the net doping concentration is independent of local dislocation density, but that MIS dark current varies linearly with dislocation density. No evidence for impurity segregation to dislocations was observed between the low and high dislocation density region. Deformed HgCdTe shows a larger decrease in the electron mobility after low temperature plasma hydrogenation than do undeformed samples. Dislocation density may influence the hydrogen solubility in these samples. Collectively, both the MIS and Hall results suggest dislocations themselves do not contribute to the carrier concentration in HgCdTe. (Edited author abstract) 22 refs.

## Electrochemistry

**093521 PHOTOELECTROCHEMISTRY OF CADMIUM SULFIDE. 1. REANALYSIS OF PHOTO-CORROSION AND FLAT-BAND POTENTIAL.** The photoelectrochemical behavior of cadmium sulfide depends strongly on the pretreatment of the electrodes. Sulfur, the main photocorrosion product of CdS, changes the potential drop across the Helmholtz double layer and shifts the flat-band potential of CdS in the anodic direction. Removal of sulfur from the surface is possible by prepolarizing the electrode at about  $-1.1$  V(SCE) in the presence of oxygen. The flat-band potential of the clean (0001) Cd surface has been determined to about  $-1.8$  V(SCE) in the dark. Illumination of the electrode leads to surface-state charging due to formation of S<sup>-</sup>, the intermediate in the formation of both possible photooxidation products: S<sup>0</sup> in the absence of oxygen and SO<sub>4</sub><sup>2-</sup> in the presence of oxygen. (Author abstract) 44 refs.

Meissner, Dieter (Inst fuer Solarenergieforschung, Hanover, West Ger); Memming, Ruediger; Kastening, Bertel. *J Phys Chem* v 92 n 12 Jun 16 1988 p 3476-3483.

**093522 PHOTOELECTROCHEMISTRY OF CADMIUM SULFIDE. 2. INFLUENCE OF SURFACE-STATE CHARGING.** The energy bands at the surface of clean CdS become unpinned upon illumination and are shifted in the anodic direction by several hundred millivolts. The same effect occurs in the dark after addition of the oxidized species of certain redox systems whose standard potentials are located in the bandgap of CdS. A model is presented in which the band movement is interpreted by positive charging of surface states. In the case of light excitation a hole in the valence band is captured by the surface state, in the case of a suitable oxidizing agent the surface state is charged by direct electron transfer from this state to the acceptor in the electrolyte. The potential dependence of photocurrents and dark currents can be explained semiquantitatively in terms of charge transfer via surface states. (Edited author abstract) 13 refs.

**093523 CHARACTERIZATION OF CdS THIN FILMS ELECTRODEPOSITED BY AN ALTERNATING CURRENT ELECTROLYSIS METHOD.** Cadmium sulfide thin films have been electrodeposited by a method involving the application of a square wave potential to tin oxide electrodes immersed in an electrolyte containing cadmium sulfate and sodium thiosulfate. To elucidate the main electrochemical processes that occur during the positive and negative parts of the applied wave, a voltammetric study has been carried out. The morphology and the structural and optical properties of these films are analyzed. Electrical properties before and after annealing are reported. (Author abstract) 12 refs.

Fatas, E. (Univ Autonoma de Madrid, Madrid, Spain); Herrasti, P.; Arjona, F.; Garcia Camarero, E. *J Electrochem Soc* v 134 n 11 Nov 1987 p 2799-2801.

**093524 PHOTOELECTROCHEMICAL DEPOSITION AND PROPERTIES OF THIN-FILM CADMIUM TELLURIDE.** Thin-film cadmium telluride has been deposited cathodically on titanium in a photoelectrochemical cell (PEC) using a propylene carbonate solution of Cd II and tri-n-butylphosphine telluride (BPT) at 100°C. Illumination of the cathode enhances the cathodic current relative to that observed during the dark process. Furthermore, the current under illumination decreases more slowly than it does for the dark process, providing thicker films in a shorter time. Under illumination, the Te:Cd ratio of the film is independent of light intensity and

applied potential in the range  $-0.8$  to  $-1.4$  V (Ag-AgCl reference electrode). This ratio and the deposition current depend on the concentration of cadmium ion relative to that for BPT. Photovoltaic cells (PVC) have been fabricated. Light-to-electric-power conversion efficiencies as high as 5.2% have been achieved thus far over small surface areas. The bandgap of the CdTe film is determined to be 1.44 eV. (Edited author abstract) 15 refs.

**093525 ON THERMALLY ACTIVATED ELECTRON MOBILITY IN N-TYPE  $\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$ .** It is shown that the assumption of a thermally activated mobility in n-type  $\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$  is not supported by the available experimental evidence. In particular, the criticism of our previous paper by Gebhardt and co-workers is shown to be unfounded. The hypothesis of magnetic freeze-out is well supported by experimental data and by the similarity to the behaviour of InSb. (Author abstract) 10 refs.

Herlach, Fritz (Katholieke Univ Leuven, Louvain, Belg); De Vos, Godelieve. *J Phys C Solid State Phys* v 20 n 34 Dec 10 1987 p 5901-5903.

**093526 BOUND STATES IN INVERSION LAYERS ON p- $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ : SELF-CONSISTENT RESULTS.** Bound states in inversion layers on p- $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  are calculated self-consistently taking the interaction of the conduction and valence bands through the surface potential and the  $\kappa$ -p interaction explicitly into account. Three different models of the band structure are compared and numerical results are presented. It is shown that the four-band spinless model, proposed by Zawadzki for InSb, is not appropriate to describe the bound states on  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  and more elaborate models, which take the spin-orbit interaction into account, have to be used. (Author abstract) 16 refs.

**093527 MODIFICATION OF CdMnTe REFLECTIVITY SPECTRA BY Mn DENSITY OF STATES.** We present a simple model which interprets main features of the blurring of the CdMnTe reflectivity spectra with increasing the manganese concentration. We have made an attempt to determine the energy position of the unoccupied Mn 3d states. They are located at about 2.9 eV above the valence band maximum. (Author abstract) 15 refs.

Oleszkiewicz, J. (Univ Jagiellonski, Cracow, Pol); Kisiel, A.; Rodzik, A. *Solid State Commun* v 63 n 2 Jul 1987 p 77-80.

**093528 STUDY OF DEEP LEVELS IN NARROW-GAP SEMICONDUCTORS  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  BY ATSC METHOD.** The deep levels in narrow-gap semiconductors  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  ( $x=0.195$  approximately 0.275) are investigated using the alternating thermal stimulated current (ATSC) method. The physical properties of the deep levels in  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  are discussed. The experimental results show that the ATSC method is an effective way to investigate the deep levels in narrow gap semiconductors  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ . (Author abstract). 11 Refs. In Chinese.

Lin, He (Acad Sinica, China); Tang, Dingyuan. *Hongwai Yanjiu A-Ji* v 7A n 4 1988 p 267-273.

**093529 DEEP LEVELS IN n-TYPE  $\text{HgCdTe}$ .** Deep levels in both bulk and LPE liquid phase epitaxy n-type  $\text{Hg}_{0.685}\text{Cd}_{0.315}\text{Te}$  have been studied by deep level transient spectroscopy (DLTS) between 78 and 170 K using metal-insulator-semiconductor (MIS) capacitors. One major acceptor-like electron trap was observed in the

depletion region of the semiconductor with an energy level at  $E_c-85$  meV, or  $E_c-0.3E_g$ . The electron capture cross section was found to be independent of the temperature and has an average value of  $1 \times 10^{-16}$  cm<sup>2</sup>. The ratio of the trap concentration ( $N_t$ ) to the shallow donor concentration ( $N_d$ ) in both the bulk material and the LPE film was found to be close to 1. A general expression allowing numerical calculation of the capacitance transient due to the thermal ionization of traps in MIS capacitors with any value of  $N_t/N_d$  is also given. (Author abstract) 13 refs.

Chen, M.C. (Texas Instruments Inc, Dallas, TX, USA); Goodwin, M.W.; Polgreen, T.L. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 484-489.

**093530 DEEP LEVELS IN CdTe.** We have used a variety of complementary techniques to study electronic trapping levels that are far from either band edge in CdTe. These deep levels play an important role in determining the electrical properties of the material. We have studied and attempted to identify levels due to specific defects and those due to either intentional or unintentional dopants. These findings have been correlated with information from the literature. The methods used included both DC and AC photoconductivity, photocurrent induced transient spectroscopy (PITS), and deep level transient spectroscopy (DLTS). CdTe samples doped with aluminum, indium, tin, cesium, and phosphorus, as well as nominally undoped sample have been examined. Fifteen different levels have been identified as related to these impurities. (Author abstract) 23 refs.

Kremer, R.E. (Oregon Graduate Cent, Beaverton, OR, USA); Leigh, W.B. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 490-496.

**093531 OPTICAL NONLINEARITY OF BOUND SINGLE AND MULTIEXCITONS IN CdS.** By means of two-beam experiments, the transmission properties of highly excited CdS crystals of different thicknesses ( $6 \mu\text{m}$  to  $1 \text{ mm}$ ) have been investigated in the energy regime of the bound single and multiexcitons. Induced transmission was observed in the whole considered region for lower pump intensities. However, nonlinearly growing absorption counteracts this increase for rising excitation densities. Excitation spectroscopy of select points of the transmission spectrum and the temperature dependence of the observed phenomena show that bound single and multiexcitons as well as charge transfer processes play an important role in determining these properties of CdS samples. However, intraband transitions of free electrons and two step-processes of free single and biexciton's generation via bound exciton states have also to be discussed. (Author abstract) 7 refs.

Hoening, T. (Technische Univ Berlin, Berlin, West Ger); Gutowski, J.; Broser, I. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 576-580.

**093532 DEGENERATE AND NONDEGENERATE FOUR-WAVE MIXING AND LASER-INDUCED GRATINGS IN CdS.** In this contribution we determine for the first time the diffusion length of degenerate and non-degenerate carriers in CdS as a function of density and temperature; we observe and analyse switching processes in self-diffraction and report on nondegenerate four-wave mixing. 10 refs.

## Encapsulation

**093533 COPOLYMERIZATION OF VINYL MONOMERS ON THE SURFACE OF CdS AND PHOTOCONDUCTIVITY PROPERTIES OF RESULTING**

**COMPOSITES.** The reaction behaviour of CdS encapsulated copolymer composites, their photoconductivity, and the mechanism of their photosensitivity were investigated. The results indicated that the reactivity ratios of the monomers for the encapsulated copolymer are considerably different from those of the homopolymer during encapsulation. The photoconductivities showed a marked increase over that of CdS alone. These characteristics were explained with the distribution state of the energy levels of the traps and also with the increase of the characteristic temperature. Similar results were also observed for the light intensity index derived from the dependence of the photocurrent upon irradiation intensity. (Edited author abstract) 18 refs.

## Etching

**093534 CHEMICAL INTERACTIONS AT THE INTERFACE BETWEEN CADMIUM TELLURIDE AND AQUEOUS SOLUTIONS OF  $\text{HCl-HNO}_3$  MIXTURES.** The rate of solution of CdTe in  $\text{HCl-HNO}_3\text{-H}_2\text{O}$  solutions was investigated. Experiments were carried out on high-resistance samples of p-type single crystals of cadmium telluride. A quantitative characteristic of the etching process is the rate of solution of the semiconductor. Diagrams were constructed for the etching rate of CdTe as a function of the reagent composition at 293 and 303 K. From the diagrams it is evident that the cadmium telluride solution rate rises with an increase in the nitric acid concentration. 8 refs.

Sava, A.A. (Acad of Sciences of the Ukrainian SSR, USSR); Tomashik, V.N.; Mizetskaya, I.B.; Tkach, V.N. *J Appl Chem USSR* v 60 n 1 pt 1 Jan 1987 p 29-33.

**093535 VOLUME ALLOYING CADMIUM TELLURIDE CRYSTALS WITH SILVER IN SELECTIVE ETCHING.** Selective etching of specimens of p-CdTe in silver-bearing etching agents results in the introduction of rapidly diffusing Ag<sub>i</sub> donors into the volume of the material. This leads to a large reduction of the concentration of free carriers. (Author abstract) 5 refs.

## Growth

**093537 EPITAXIAL GROWTH OF CdTe ON InSb(100) BY RF SPUTTERING.** Cadmium telluride is deposited epitaxially by rf sputtering on the clean surface of InSb(100) substrate from which the surface native oxide has been etched off in advance by  $\text{H}_2$  plasma treatment. The crystalline quality of CdTe films which depends on the substrate temperature is evaluated by means of the optical reflectance, Raman scattering and RHEED pattern measurements. CdTe films prepared at temperatures of 250-300°C are deposited epitaxially, but those at 100°C are not. (Author abstract) 8 refs.

Phys Part 2 v 26 n 9 Sep 1987 p 1437-1439.

**093538 GROWTH AND CHARACTERISATION OF  $\text{Cd}_x\text{Hg}_{1-x}\text{Te}$  GROWN BY LPE USING A NOVEL SLIDING BOAT.** A significant problem in the growth of CMT by Te-solution LPE is associated with melt residues on the layers. This paper describes the development and use of a sliding boat which tilts the substrate after growth to remove these droplets. The reproducibility of the process depends on control of Hg vapor pressure and the composition of the melts. A relationship between the x-value of the layers and the Cd and Hg content in the melts has been established. Variations in x are  $\pm 0.002$ , for  $x \approx 0.22$ , over  $13 \times 13 \text{ mm}^2$  areas. Various chemical analysis techniques have been used to assess the purity of the layers. Electrical characterization of the layers has shown them to be p-type as grown, as expected, and suitable annealing in Hg vapor converts them to n-type. (Author abstract) 30 refs.

**093539 BORON-SEGREGATION IN CZOCHRALSKI-GROWN CdTe.** Chemical analysis of CdTe ingots grown by the liquid encapsulated Czochralski technique using  $\text{B}_2\text{O}_3$  encapsulant show that the material contains up to 90 ppm boron and that the boron distribution is non-uniform. High concentrations are found at twin and grain boundaries. Boron-rich precipitation is also observed. The observation of low carrier concentrations ( $n_{77\text{K}} = 8 \times 10^{14} \text{ cm}^{-3}$ ) and high electrical mobility ( $\mu_{77\text{K}} = 4800 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ ) in this material also supports the thesis that most of the boron is not electrically active. (Author abstract) 19 refs.

**093540 NEW EPITAXIAL RELATIONSHIPS IN THE DEPOSITION OF CdS ONTO CdTe.** The present paper reports on the epitaxial growth of CdS onto  $\{111\}\text{A}$ ,  $\{1\bar{1}1\}\text{B}$  and  $\{221\}$  oriented single crystal CdTe substrates by vacuum evaporation. These observations were made in the course of a wider investigation of the CdS/CdTe solar cell in which structural aspects were investigated along with other parameters such as contacts, electrical properties, doping, etc. The epitaxial layers were grown on highly resistive undoped CdTe substrates and were intended only as a study of the epitaxial growth of CdS onto CdTe. Clearly these structures would have had an unacceptably high series resistance and no attempt was made to fabricate device structures from them (by the evaporation of contacts, etc.) or to measure their electrical characteristics. 19 refs.

**093541 LIQUID PHASE EPITAXY OF  $\text{Cd}_x\text{Hg}_{1-x}\text{Te}$  ( $0.5 < x < 1$ ) AND PHASE DIAGRAM DETERMINATION.** Cd-rich  $\text{Cd}_x\text{Hg}_{1-x}\text{Te}$  layers were grown onto CdTe and  $\text{Cd}_{0.96}\text{Zn}_{0.04}\text{Te}$  substrates by liquid phase epitaxy from a Te-rich solution in an open tube apparatus. Mercury vapor losses were carefully controlled in a specially designed sliding graphite reactor. Solid solution compositions between  $x=0.5$  and  $x=1$  were obtained. An expression for the segregation coefficient of cadmium as a function of x was obtained, viz.:  $k_{\text{Cd}} = x(1.080 - x)/0.080$ . The phase diagram of the ternary alloy in the Te corner was inspected and a method for determining the liquidus temperatures from the kinetics of epitaxial growth is presented; two isotherms  $T=460^\circ\text{C}$  and  $T=480^\circ\text{C}$  have been determined. The effect of the degree of supercooling on the layer morphology was studied. (Author abstract) 19 refs.

**093542 CZOCHRALSKI GROWTH OF CdTe AND**

**CdMnTe FROM LIQUID ENCAPSULATED MELTS.** CdTe and CdMnTe boules with diameters up to 50 mm and weighing up to 1 kg have been grown by liquid-encapsulated Czochralski (LEC) pulling from  $\text{B}_2\text{O}_3$ -encapsulated melts. LEC CdTe boules were always characterized by a high incidence of twinning and polycrystallinity. However, by alloying with manganese at compositions up to 0.20 mole fraction MnTe, growth proceeding by means of alternating bands or lamellae perpendicular to the  $\langle 111 \rangle$  growth axis was achieved. Preliminary attempts to control melt convection by the application of magnetic fields to LEC CdTe and CdMnTe melts indicate that field intensities much greater than 2000 G will be required. (Edited author abstract) 21 refs.

**093543 AUTOMATED SYSTEM FOR METAL ORGANIC VAPOUR-PHASE EPITAXY.** In Metal Organic Vapor Phase Epitaxy, metal-organic compounds are transported, in the vapor state, to a heated reaction site, or susceptor, where the formation of the desired material takes place. A particular application being studied in this laboratory is the growth of cadmium mercury telluride (CMT). In general, by controlling the times during which particular vapors are allowed to flow into the MOVPE reactor, one can grow alternating layers of different, carefully controlled compositions (heterostructures). In the particular example of CMT, the reaction is followed by an annealing stage which results in a homogeneous material of controlled composition; the whole method being known as the Interdiffused Multilayer Process (IMP). 2 refs.

Mills, A.D.; Whiffin, P.A.C. *Annu Rev Philips Res Lab* 1986 p 121-123.

**093544 CdTe JUNCTION PHENOMENA.** Five main areas of research on CdTe junction phenomena are reviewed: (1) the effect of surface etching and stoichiometry on the properties of Schottky barriers and heterojunctions with CdS and indium tin oxide (ITO) formed on p-type CdTe crystal; (2) the major junction transport models applicable to CdS/CdTe, CdS/ZnCdTe, ZnO/CdTe and ITO/CdTe junctions; (3) the deposition and control of the properties of p-type CdTe films using close-spaced vapor transport and the characteristics of CdS/CdTe junctions prepared with these films; (4) the successful doping of p-type CdTe films during growth by ion-beam doping methods; and (5) methods of preparing low-resistivity contacts to p-CdTe. (Edited author abstract) 72 refs.

**093545 X-RAY DIFFRACTION STUDIES OF CdTe GROWN ON InSb.** Cadmium telluride layers, grown on InSb substrates which were  $(100) 2^\circ$  oriented towards  $(110)$ , were examined using double crystal X-ray diffraction in conjunction with secondary ion mass spectrometry and photoluminescence. The layers were grown by organometallic vapor phase epitaxy at atmospheric pressure. The crystal quality of the CdTe is shown to be related to the substrate temperature and the nature of the surface prior to growth. Growth on diethyltelluride stabilized InSb substrates resulted in epitaxial layers with a misorientation of about  $235 \text{ arc sec}$  with respect to the substrates. On the other hand, layers followed the orientation of the substrate, when dimethylcadmium stabilized InSb was used. Growth at  $350^\circ\text{C}$  resulted in the smallest X-ray rocking curve (DCRC), with a full width at half maximum (FWHM) of about  $20 \text{ arc sec}$ . Secondary ion mass spectrometry and photoluminescence data complement the results of this X-ray diffraction study. (Author abstract) 14 refs.

**093546 LIQUID PHASE EPITAXIAL GROWTH OF  $\text{Cd}_x\text{Hg}_{1-x}\text{Te}$  FROM SEMI-INFINITE Hg-RICH MELT.** Semi-infinite Hg-rich melt in the vertical dipping configuration was used to grow thin layers of  $\text{Cd}_x\text{Hg}_{1-x}\text{Te}$  onto CdTe and cadmium telluride on sapphire (COS) substrates. The experimental procedure is described in detail. The melt, weighing about 10 kg, was constantly held in the temperature range  $475\text{--}490^\circ\text{C}$ . Cooling rates of  $3.6\text{--}5.4^\circ\text{C/h}$  were employed. Surface morphology of the layers when examined by using an optical microscope revealed incidents of substrate-replicated twinnings. X-ray diffraction and back reflection Laue technique showed the layers to be monocrystalline and of good epitaxial quality. The technique EDX was used to investigate the compositional variations through the layer. All as-grown layers were n-type ( $n = 2 \times 10^{15}\text{--}1.4 \times 10^{16} \text{ cm}^{-3}$  and  $\mu_H = 3 \times 10^4\text{--}3 \times 10^5 \text{ cm}^2/\text{V.s}$  at 77 K for x in the range 0.221-0.24). Carrier mobility profiles through the layers were also studied using the successive layer removal/Hall measurements (step and etch) technique. (Author abstract) 34 refs.

**093547 EFFECT OF THE SUBSTRATE MISMATCH ON THE LPE OF  $\text{HgZnTe}$  AND  $\text{CdZnTe}$  LAYERS.** The effect of the lattice mismatch is studied on the processes which occur during the contact between supersaturated Hg-Zn-Te growth solutions and the CdZnTe substrates. The influence of these processes on the characteristics of the HgZnTe layers is outlined. Similar behavior of the two Hg-rich solid solutions is demonstrated when heterostructures with the same lattice mismatch are compared. In order to find out how the presence of Hg in the layers influences the lattice mismatch phenomena, results are compared with those of another heterostructure based on II-VI solid solutions:  $\text{Cd}_{1-y}\text{Zn}_y\text{Te}/\text{Cd}_{1-z}\text{Zn}_z\text{Te}$ . 23 refs.

**093548 GROWTH OF ORIENTED TELLURIUM-DOPED CADMIUM SULFIDE SINGLE CRYSTALS FROM THE VAPOR.** Single crystals of Te-doped CdS ( $\text{Te} = 0.02\text{--}0.35 \text{ wt.}\%$ ) have been grown in the form of cylinders with volumes up to  $17 \text{ cm}^3$  by the method of contactless growth on oriented CdS (0001) inoculates. The Te content along the length of the crystal decreases by a factor of 1.5 to 2. During sublimation a preferred diffusion of tellurium into the cold part of the vial is observed. The electric and optical properties of the crystals vary as a function of the tellurium content. In Russian. 7 refs.

**093549 GROWTH AND CHARACTERIZATION OF  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$  SINGLE CRYSTALS.**  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$  crystal, which is a semimagnetic semiconductor, is a new semiconductor compound receiving much attention not only for use in optical magnetic field/electric current meters but also as a substrate for the epitaxial growth of  $\text{Hg}_{1-y}\text{Cd}_y\text{Te}$ , which is used for infrared detectors. In our research, we grew  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$  crystals measuring 30 to 40 mm in diam with a composition range of 0.10 to 0.19, and evaluated the crystallinity, electrical properties, optical properties, magneto-optical properties, etc., of the resulting crystals. As a result we discovered that the Mn composition changed in the growth direction at an effective segregation coefficient ( $k_{\text{eff}}$ ) of 0.93, and that it was extremely uniform, with fluctuation on the wafer surface of only 1% or less. The average EPD (etch pit density) on the wafer surface was  $3\text{--}4 \times 10^4 \text{ cm}^{-2}$ , and excellent crystallinity was observed with no cell structures or lineages. Using double-crystal x-ray rocking curve measurements, it was confirmed that the increase in the Mn concentration reduced the full width at half maximum

(FWHM) and that the crystal perfection surpassed that of CdTe crystals. Excellent infrared transmission of 50% or more in the 2 to 25  $\mu\text{m}$  wavelength range was obtained. (Edited author abstract) 13 refs.

**093550 X-RAY CHARACTERIZATION OF LPE MERCURY CADMIUM TELLURIDE.** X-ray topography and double crystal diffractometry investigations have been performed on  $\text{Hg}_{0.78}\text{Cd}_{0.22}\text{Te}$  epilayers grown on substrates by liquid phase epitaxy. Topographs showed only misfit dislocations and dislocation cellular arrangements. Double crystal rocking curves exhibited considerably narrower Bragg peak half-widths than previously reported; half-widths as small as 20 arc sec were indeed observed. These results demonstrate that the present epilayers are characterized by a very good crystal quality. (Author abstract). 9 Refs.

**093552 HIGH CAPABILITY QUASI-CLOSED GROWTH SYSTEM FOR ISOTHERMAL VAPOUR PHASE EPITAXY OF  $(\text{Hg,Cd})\text{Te}$ .** A high capability open growth system for isothermal vapor phase epitaxy has been developed. The system is based on a quasi-closed quartz container with multiple growth bins. The container is placed inside a quartz tube which is filled with multiple growth bins. The container is placed inside a quartz tube which is filled with  $\text{H}_2$  or evacuated. The system enables epitaxial  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  layers from 1 to 1000  $\mu\text{m}$  in thickness to be grown on bulk CdTe,  $\text{Cd}_{1-x}\text{Zn}_x\text{Te}$  and alternative substrates such as mica, sapphire and GaAs. The layer morphology is entirely determined by the substrate quality. Several methods of layer compositional profile control are proposed. A process duration of one day (including low temperature annealing) has been developed to fabricate layers of 3-30  $\mu\text{m}$  thickness and up to about 1000  $\text{cm}^2$  in total area as a basis for manufacturing PV, PC and PEM IR detectors. (Author abstract). 11 Refs.

**093553 MAGNETO-OPTICAL PROPERTIES OF  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$  MULTILAYERED STRUCTURE PREPARED BY IONIZED-CLUSTER BEAMS.** The film growth of  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$  with a multilayered structure was performed by ionized-cluster beam deposition technique, and their magneto-optical properties have been investigated. It was found that the films had a periodical structure from the results of Auger electron spectroscopy and x-ray diffraction measurements. In the Faraday rotation spectra of the multilayered structures, two band-edge dispersions corresponding to the well and barrier layers were observed. As the well width decreases, the dispersion peak for the well layer shifts toward higher photon energies and becomes higher, while the dispersion for the barrier layer remains unchanged. This can be explained by a quantum size effect in a superlattice. 17 refs.

MAG-23 n 5 Sep 1987, INTERMAG '87: Int Magn Conf, Tokyo, Jpn, Apr 14-17 1987 p 3214-3216.

**093554 SUPERLATTICES OF II-VI SEMICONDUCTORS.** Superlattices and microstructures involving II-VI semiconductors have been the subject of a great deal of interest for application to optoelectronics in the infrared and visible. The techniques of material fabrication provided by molecular beam epitaxy (MBE) and metalorganic chemical vapor deposition (MOCVD) make it possible for us to conceive of a number of new structures that could have application in the optoelectronics arena. Superlattices and heterojunction structures involving some of the wide band gap II-VI compounds such as CdTe, ZnTe, and ZnSe could bring to reality the dream of making wide band gap visible light emitters. (Author abstract) 25 refs.

**093555 CRYSTAL GROWTH OF LARGE-AREA SINGLE-CRYSTAL CdTe AND CdZnTe BY THE COMPUTER-CONTROLLED VERTICAL MODIFIED-BRIDGMAN PROCESS.** Recent improvements in the growth of 5-cm diameter CdTe and  $\text{Cd}_{0.96}\text{Zn}_{0.04}\text{Te}$  boules by the computer-controlled vertical modified-Bridgman (VMB) process are described. The most significant improvements in crystal quality are attributed to a combination of new furnace design, improved temperature-profile control, and in-situ post-growth thermal annealing of boules. In addition, thermal diffusivities of CdTe and  $\text{Cd}_{0.96}\text{Zn}_{0.04}\text{Te}$  were measured as a function of temperature in the vicinity of the melting points. The effect of this critical parameter on the solid-liquid interface shape and position was determined with the aid of a finite-element numerical thermal model. (Author abstract) 8 refs.

Sen, S. (Santa Barbara Research Cent, Goleta, CA, USA); Konkel, W.H.; Tighe, S.J.; Bland, L.G.; Sharma, S.R.; Taylor, R.E. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 111-117.

**093556 HIGH QUALITY, SINGLE CRYSTAL CdTe GROWN BY A MODIFIED HORIZONTAL BRIDGMAN TECHNIQUE.** High quality CdTe single crystals with low etch pit densities (EPDs) and subgrain-free structure have been produced by a multizone horizontal Bridgman technique. The volume of single crystal is up to 75% of the boule. Experimental results have demonstrated that growth stress plays a critical role in the reduction of dislocation densities. X-ray topography data confirm the improvement in crystalline perfection: EPD counts as low as  $2 \times 10^4/\text{cm}^2$  are observed and double crystal X-ray rocking curves have FWHMs as low as 10 arc sec. (Author abstract) 11 refs.

**093557 CRYSTAL GROWTH AND CHARACTERIZATION OF CdTe FROM THE MELT UNDER CONTROLLED Cd PARTIAL PRESSURE.** CdTe crystals were grown by a modified Bridgman technique with the Cd pressure kept equal to the equilibrium value. 6N purity Cd and Te were used to synthesize the CdTe. Metallographic observation of the as-grown crystals showed that no inclusions were present. The deviation of composition from stoichiometry was investigated by microprobe analysis and was found to be below the limit of detection. The Cd and Te distribution obtained by microprobe scanning was homogeneous. Microscopic observation of preferentially etched crystals showed a dislocation density of  $10^3$ – $10^5 \text{ cm}^{-2}$ . The structural perfection is good, as seen from X-ray diffraction Laue patterns. The lattice parameter determined by X-ray

diffraction is 6.4846 Angstrom. Our CdTe crystals have been used as substrates for hot wall epitaxial growth of CdTe films and for the fabrication of temperature sensors coupling with optical fibers. (Edited author abstract) 5 refs.

**093558 STATE OF THE ART OF LPE HgCdTe AT LIR.** LPE has become an established technique for the growth of CMT layers. In this paper we discuss in detail the LPE growth of CMT from Te-rich solutions in an open-tube horizontal-slider apparatus, based on LIR's experience. Different physical parameters (vapor pressure, surface tension), apparatus design, and experimental procedure (thermal cycle, crystallization path, growth kinetics) are described. The physical parameters of undoped-CMT layers grown by LPE are given: surface morphology, defect density, composition, thickness, electrical properties (as-grown and n-type annealed). Good uniformity and reproducibility in both 3-5  $\mu\text{m}$  and 8-12  $\mu\text{m}$  ranges has been established over more than 500 layers/year grown in our pilot line. This paper presents a new and sophisticated structure entirely grown by LPE = CMT/CZT/CZT, the advantages of which are discussed. (Author abstract) 11 refs.

**093559 PROPERTIES OF DOPED II-VI FILMS AND SUPERLATTICES GROWN BY PHOTOASSISTED MOLECULAR BEAM EPITAXY.** A new film growth technique, photoassisted molecular beam epitaxy (PAMBE), has been used to prepare substitutionally doped II-VI semiconductor compounds. This epitaxial growth technique differs from conventional MBE in that the substrate is illuminated during the entire film growth process. We have used this new technique to prepare conducting layers of CdTe and CdMnTe. In our experiments, the output from an argon ion laser is used as the source of illumination. In and Sb were employed as n-type and p-type dopants, respectively. Conducting n-type CdMnTe:In-CdTe superlattices have also been grown along with doped CdMnTe:Sb-CdTe structures. The structural, electrical, and optical properties of the conducting epilayers were investigated by means of double crystal X-ray diffraction, Van der Pauw Hall effect measurements, and low temperature photoluminescence. (Author abstract) 16 refs.

Giles, N.C. (North Carolina State Univ, Raleigh, NC, USA); Bicknell, R.N.; Harper, R.L.; Hwang, S.; Harris, K.A.; Schetzina, J.F. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 348-353.

**093560 SURFACE NUCLEATION KINETICS OF MOLECULAR BEAM EPITAXIAL DOPED (001) AND (111) CdTe.** Reflection high-energy electron diffraction desorption studies have been used to determine the reaction kinetics of (001) and (111) CdTe surfaces. The addition of Sb was found to impede epitaxy on the (111) surface, but to be compatible with epitaxy on the (001) surface. The desorption of Cd, Te and Sb from (001) CdTe were observed to follow an Arrhenius relationship with activation energies of 7.70, 1.95 and 3.69 eV, respectively. Reflection high-energy electron diffraction intensity oscillations were observed for the growth of (001) CdTe and used to study interface smoothness. The effect that

photo-assisted molecular beam epitaxy has on the reaction of Sb doping of (001) CdTe was determined. (Author abstract) 17 refs.

Benson, J.D. (Georgia Inst of Technology, Atlanta, GA, USA); Summers, C.J. *J Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 354-361.

**093561 MBE p-TYPE  $Hg_{1-x}Cd_xTe$  GROWN ON THE (110) ORIENTATION.** Reported here for the first time is the successful MBE growth of  $Hg_{1-x}Cd_xTe$  ( $0.16 < x < 0.41$ ) on the nonpolar (110) face of CdTe substrates. (110) HgCdTe epilayers always show p-type conductivity at 77 K with high hole concentration ( $10^{16}$ – $10^{19} \text{ cm}^{-3}$ ) and good structural quality, as determined by double-crystal X-ray rocking curve (100-180 arc sec). We also report that during the MBE growth process, the rate of Hg vacancy formation on the (110) orientation is greater than on the more conventional (111)B and (100) orientations. The unique material properties of (110) HgCdTe may find application in the fabrication of photovoltaic detectors, light emitting diodes, and multiple quantum wells for nonlinear optics applications. (Author abstract) 20 refs.

**093562 GROWTH AND CHARACTERIZATION OF HIGH-QUALITY CdTe EPILAYERS ON GaAs SUBSTRATES BY HOT-WALL EPITAXY.** CdTe layers with a thickness of 3-15  $\mu\text{m}$  are grown on (100) oriented GaAs substrates in a hot-wall-epitaxy system. As a quality criterion, the 1.8 K near band edge photoluminescence is measured. We observe sharp bound-exciton lines. Their full width at half maximum (FWHM) is decreasing with increasing thickness of the layers, revealing a decreasing density of extended lattice defects at the surface. The FWHM of the dominating acceptor bound exciton emission from a 15  $\mu\text{m}$  thick layer is 0.18 meV. This value is close to the FWHM obtained with high purity CdTe. A small shift of 0.5 meV of the epilayer exciton line energy relative to the bulk emission is independent of the layer thickness. (Author abstract) 12 refs.

**093563 GROWTH OF (111) AND (100) CdTe FILMS ON (100) GaAs SUBSTRATES BY HOT WALL EPITAXY.** Both (111) and (100) oriented CdTe films have been grown on (100) GaAs substrates by hot wall epitaxy. X-ray diffraction and photoluminescence measurements indicate that the (111) material is of superior crystal quality with typical X-ray FWHM values ranging between 60 and 80 arc sec. SIMS analysis shows gallium in these layers at a level of mid  $10^{14} \text{ atoms/cm}^3$ . (Author abstract) 13 refs.

**093564 CHEMICAL STRUCTURE OF MICROCRYSTALLINE CdTe FILMS GROWN BY RF SPUTTERING.** We have applied X-ray photoemission and Auger spectroscopy techniques to the study of the stoichiometric properties of CdTe thin films grown by RF sputtering. The microcrystalline films were deposited on glass substrates held at temperatures between 50 and 200°C. They contain a mixture of the cubic (zinc-blende) and hexagonal (wurtzite) phases which are nearly stoichiometric. By using bulk and surface sensitive photoemission geometries it is shown that a tellurium oxide overlayer is

always formed after exposure to air. A simple calculation shows that this overlayer is at most 10 Angstrom thick. Cadmium seems to be insensitive to the presence of oxygen, as demonstrated by the absence of shifted Cd peaks in the X-ray spectra. It is shown that the low kinetic energy features in the Auger spectra ( $< 100 \text{ eV}$ ) are very sensitive to the oxide overlayer and contamination. (Author abstract) 11 refs.

**093565 TEMPERATURE DEPENDENCE OF THE HALL EFFECT OF THM-GROWN  $Hg_{1-x}Cd_xTe$  CRYSTALS.** The  $Hg_{1-x}Cd_xTe$  crystal was grown by THM and the crystal obtained was 10 mm in diameter and about 50 mm in length. The mid-portion, two-thirds of the total length, has good homogeneity as  $x = 0.20 \pm 0.02$  for the axial and  $x = 0.200 \pm 0.004$  for the radial direction. The type-conversion temperature  $T_c$  for the Hall coefficient shifted linearly to higher value as  $x$  increased, and the linearly fitted curve can be expressed as  $T_c = 1048x - 105$ . We presented  $\mu_H(300 \text{ K})/\mu_H(77 \text{ K}) \approx 19$  as the minimum value of the mobility ratio which may give a criterion to be related with the crystal quality for the as-grown p-type MCT in the temperature range. (Author abstract) 13 refs.

**093566 STUDIES OF IMPURE CADMIUM OXIDE SEMICONDUCTORS USING NMR, EPR AND CONDUCTIVITY MEASUREMENTS.** Cadmium oxide semiconductors were prepared by heating CdO which also contained hydroxide and carbonate species formed on storage. Reaction of the impurities on heating, and high temperature annealing, produced an unusually wide range of electrical conductivities, EPR spectra and NMR spectra. Changes in EPR spectra were correlated with the  $^{113}\text{Cd}$  shift, which was shown to be proportional to the square root of the relaxation rate, and also proportional to the line width. This allowed the Knight shift contribution to the resonance position to be separated from the paramagnetic shielding (due to covalency). (Edited author abstract) 40 refs.

**093568 PICOSECOND PHOTOLUMINESCENCE FROM BOUND EXCITONS IN  $Cd_{1-x}Zn_xTe$ .** Picosecond lifetimes of donor- and acceptor-bound excitons have been observed by time correlated single photon counting with high spectral resolution. The lifetimes increase with localized energy as expected for radiative transitions and are predicted reasonably well by both the Sanders-Chang and Rashba-Gurgenishvili theories. Lifetimes measured at the main photoluminescence peak for three other  $Cd_{1-x}Zn_xTe$  samples with  $x = 0, 0.023$  and  $0.19$  decrease with increasing  $x$ . (Author abstract) 22 refs.

**093569 SOURCES AND BEHAVIOUR OF IMPURITIES IN LPE-GROWN (Cd,Hg)TE LAYERS ON CDTE(111) SUBSTRATES.** The sources of background impurities in LPE layers of (Cd, Hg)Te grown on CdTe(111) substrates are investigated using Spark-source mass spectrometry (SSMS) and secondary-ion mass spectrometry (SIMS). The principal sources of impurities were (i) the compounds HgTe and CdTe used in the LPE solution synthesis, (ii) the graphite sliding boat system and (iii) the CdTe substrate. The main impurities and their typical levels in the LPE layers were found to be Li(0.2 ppm), Na(0.3-1.0 ppm), Si(0.1-0.3 ppm), Cl(0.3-0.4 ppm) and K(0.03-0.06 ppm). To reduce the levels various changes in procedure were adopted such as cleaning of the graphite boat parts in aqua regia, the use of elemental starting materials (Hg, Cd, Te), substrate purification and the use of in-situ wash melts. The effect of Hg saturated isothermal annealing on the impurity concentrations and distribution has been studied, revealing rapid surface segregation of the Group IA impurities. The values of the distribution coefficients for several impurities have been calculated from the analytical results. (Edited author abstract) 27 Refs.

**093570 ION IMPLANTATION AND SIMS PROFILING OF IMPURITIES IN II-VI MATERIALS (HgCdTe AND CdTe).** Ions from throughout the periodic table have been implanted into HgCdTe and CdTe under a variety of conditions, and the  $\times$  atom depth distributions measured using oxygen and cesium secondary-ion mass spectrometry (SIMS). Many of these ions were implanted in the {100} crystal direction as well as in a random orientation close to {111}. Most of the HgCdTe material implanted was solid-state-recrystallized bulk  $Hg_{1-x}Cd_xTe$  ( $x = 0.19$  to  $0.35$ ) thermally processed at 350°C for 3 or 4 weeks (device-quality material) and etched prior to implantation. Ions from H to Ta were implanted at energies from 100 to 700 keV and fluences from  $10^{13}$  to  $3 \times 10^{15} \text{ cm}^{-2}$ . The SIMS technology developed for this work is discussed. SIMS sensitivity factors for HgCdTe and CdTe are shown to be the same within experimental accuracy (relative to Te). (Edited author abstract) 3 refs.

**093571 NEUTRALIZATION OF ACCEPTOR AND DONOR IMPURITIES IN HYDROGENATED CdTe.** n-Type CdTe crystals were hydrogenated by annealing under hydrogen gas at 500°C. A strong reduction in donor concentration by orders of magnitude was observed and attributed to the neutralization of donor impurities by formation of complexes with hydrogen. The diffusion profiles of deuterium were measured and analysed in terms of a neutral fast diffusing species (atomic deuterium) and a charged slow species trapped on ionized acceptors. (Author abstract) 15 refs.

**093572 CONTROL OF IMPURITY CONCENTRATION ON CdSe SURFACES.** Photoluminescence of n-type CdSe crystals at 1.8 K and above has been used to investigate the effect of photoelectrochemical etching on the impurity distribution near the semiconductor surface. The results suggest that shallow donor states are removed from the surface preferentially and hence the surface

becomes relatively intrinsic following that surface treatment. The model of non-uniform charge flow is invoked to explain phenomenon. (Author abstract) 14 refs.

**093573 CHEMICAL CHARACTERIZATION OF THE SUPERFICIAL LAYERS OF DEUTERIUM-IMPLANTED CADMIUM TELLURIDE.** This work is a part of a general investigation of the physico-chemical behavior of hydrogen in cadmium telluride. In this letter we present results of our studies by X-ray photoelectron spectroscopy (XPS) of the influence of deuterium implantation on the surface and in the surface region of cadmium telluride. As a conclusion it can be stated that: deuterium implantation removes the superficial layers of CdTe, leaving a surface depleted in tellurium; and deuterium implantation protects this surface from further oxidation.

Svob, L. (CNRS, Meudon, Fr); Ballutaud, D.; Hage-Ali, H. *J Mater Sci Lett* v 7 n 9 Sep 1988 p 949-951.

**093574 LUMINESCENCE OF Fe<sup>+</sup>-IMPLANTED CdTe.** In the 5 K photoluminescence spectra of Fe<sup>+</sup> implanted and subsequently annealed CdTe samples two emission bands, peaked at 1.03 and 1.13 eV, respectively, appear. The intensity of these lines increases linearly with the implanted Fe<sup>+</sup> dose. By varying the wavelength of the exciting laser radiation, we find that these lines are emitted from the implanted surface region only. Time resolved photoluminescence experiments reveal the time constant of the emission process. (Author abstract) 4 refs.

**093575 ELECTRICAL DOPING OF HgCdTe BY ION IMPLANTATION AND HEAT TREATMENT.** The semiconductor Hg<sub>1-x</sub>Cd<sub>x</sub>Te (CMT) is today the leading material for making infrared photodetectors. The first part of the paper is directly devoted to the general properties of junctions made by ion implantation in CMT: the structure of junctions, the effects of implantation damage, defects, annealing, and junctions made by active impurities. The second part deals with the effect of acceptor evolution in CMT after heat treatment, and a study of the kinetics is presented. In the last part of the paper it is shown that very high quality devices with very small size and large two-dimensional arrays can be achieved using an ion-implantation technique of junction formation in CMT epilayers grown by LPE. 80 refs.

**093576 DEFECTS, DIFFUSION AND ACTIVATION IN ION IMPLANTED HgCdTe.** The current understanding in junction formation by ion implantation in HgCdTe material is discussed. Two major techniques are available for junction formation: a traditional technique that consists of an ion implantation process (usually B or Be) followed by a diffusion of the irradiation-displaced mercury atoms (I<sup>2</sup>/DMD), and a classical technique of ion implantation followed by the electrical activation of the implanted species. The activation process could be of a diffused species from the implanted source, or of the as-implanted species (I<sup>2</sup>/AD or I<sup>2</sup>/D, respectively). A variety of junctions different in nature and electrical profile have been demonstrated. The best quality devices obtained so far in Hg<sub>1-x</sub>Cd<sub>x</sub>Te material with x = 0.2 from either technique are implanted-diffused in nature.

**093577 COMPARATIVE ANALYSIS OF THERMAL AND PULSE ELECTRON BEAM ANNEALING OF PHOSPHORUS IMPLANTED CADMIUM TELLURIDE.** In this paper, an analysis is extended to explain the experimental data of the different annealing processes. The profiles of implantation-induced defects as well as the temperature distribution of pulse electron beam (PEB) annealing and the phosphorus redistribution after the annealing process are calculated. The results show a strong dependence of the measured hole concentrations on the redistributed phosphorus atoms in CdTe after PEB annealing, while the implantation-induced point defects greatly affect the resultant electrical characteristics in thermally annealed samples. A logical explanation for these two cases is that the p-type conduction in the thermally annealed CdTe is compensated by cadmium vacancies, and is promoted by phosphorus interstitials, while in the PEB annealed samples phosphorus at substituted tellurium sites are easily formed due to the melting effects. **093578 DOSE RATE EFFECTS IN INDIUM-IMPLANTED Hg<sub>1-x</sub>Cd<sub>x</sub>Te.** In order to more clearly understand the effects of temperature and ion current on ion-implantation induced disorder in Hg<sub>0.7</sub>Cd<sub>0.3</sub>Te, we have implanted various doses of indium at 300 keV using different implant currents and heat sink conditions. Calculations of the transient temperature rise expected under the ion beam carried out for well heat sunk samples and for various heat sink conditions show acceptable values for moderate beam currents (1 μA cm<sup>-2</sup>). Experimental results indicate that considerable dynamic annealing occurs during implantation at temperatures greater than 77 K and that this annealing causes enhanced diffusion of indium during the implant. (Author abstract) 6 refs.

**093579 ARSENIC ION IMPLANTATION IN Hg<sub>1-x</sub>Cd<sub>x</sub>Te.** Arsenic was implanted in Hg<sub>1-x</sub>Cd<sub>x</sub>Te (0.19 ≤ x ≤ 0.23) of n-type (electron concentrations in the range from 10<sup>14</sup> to 10<sup>15</sup> cm<sup>-3</sup> at 77 K). The implantations were carried out using fluences between 10<sup>14</sup> and 5 × 10<sup>15</sup> cm<sup>-2</sup> and ion energies of 350 keV while the samples were kept at room temperature. The charge carrier concentration at 300 K was determined by analysing the infrared reflectance in the plasma resonance regions. Thermoelectric probing was also applied for determining the conduction type and the carrier concentration. Subsequently the implanted samples were annealed in saturated Hg vapour for 30 to 45 min at temperatures of 200, 300, 400 and 500°C. It was found that the As concentration profiles analysed by SIMS were not affected by annealing. The results suggest that the majority of the implanted As forms charge-compensating complexes (presumably involving oxygen) that are electrically inactive and highly immobile in the lattice. (Edited author abstract) 15 refs.

**093580 OPTICAL AND STRUCTURAL CHARAC-**

**TERIZATION OF HEAVILY BORON-IMPLANTED CdTe.** CdTe single crystals were subjected to multiple-energy boron ion implants with total doses up to 1.5 × 10<sup>16</sup> B<sup>+</sup> ions/cm<sup>2</sup>. Various diagnostic techniques were used to assess the structural and electronic properties of these crystals in their as-implanted condition and after anneals under vacuum. The degradation of crystallinity following the boron implants was clearly evident. Annealing temperatures up to 500°C were not effective to remove the damage from these heavy dose implants. The chosen boron implant conditions and annealing procedures have not produced substitutional boron donor centers. Excellent correlations were obtained for model calculations of boron projected range and implant damage profiles with the corresponding experimental parameters. (Author abstract) 26 refs.

## Laser Applications

**093581 EFFECT OF INTRINSIC DEFECTS OF THE CADMIUM SULFIDE-STRUCTURE ON THE EFFICIENCY AND OPTICAL STRENGTH OF UNCOOLED LASERS.** Cadmium sulfide is used for the fabrication of electron-beam-pumped lasers operating in the visible range of the spectrum. On the basis of a study of the electrophysical, photoluminescent and structural properties of cadmium sulfide, a model is proposed according to which an improvement in the output parameters of the laser emission is caused by an increase in the concentrations of shallow donor and acceptor levels arising with the participation of sulfur and cadmium atoms (or their vacancies). In mechanically polished cadmium sulfide crystals radiation annealing of the damaged layers was observed, as a result of which the efficiency of the lasers increased two- to threefold. In Russian. 11 refs.

## Measurements

**093584 INVESTIGATION OF p-CdTe AND p-Zn<sub>x</sub>Cd<sub>1-x</sub>Te SINGLE CRYSTALS BY ps-LASER-INDUCED GRATINGS AND BY PHOTOLUMINESCENCE.** From the measured erasure times of transient gratings created in the volume and on the surface of non-intentionally doped p-type CdTe and Zn<sub>x</sub>Cd<sub>1-x</sub>Te ( $x \leq 0.11$ ) single crystals the free-carrier lifetime and the surface recombination velocity at room temperature are determined, respectively. The erasure time of the surface grating in CdTe is found to be 130 ps, which is one order smaller than that of the volume grating. A lifetime shortening is observed in mixed crystal. Moreover, using CW-laser excitation the samples are characterized additionally by photoluminescence investigation at low temperatures to test the quality, to determine the mole fraction, and to identify impurities. The A<sup>0</sup>X-line observed is interpreted as due to a single acceptor on Te site. In the mixed crystals at  $x \geq 0.09$  the two-mode behavior of LO-phonons and an up to now not observed splitting of the A<sup>0</sup>X-line are found. (Author abstract) 20 refs.

## Mechanical Properties

**093585 MICROHARDNESS AND POLARITY IN Cd<sub>x</sub>Hg<sub>1-x</sub>Te.** The Vickers microhardness of Cd<sub>x</sub>Hg<sub>1-x</sub>Te alloys has been measured at room temperature as a function of composition and the nature of the {111} faces for different conduction types. The hardness-composition curve shows a maximum at about  $x = 0.75$ . On the {111} faces, the metal face (A face) is harder than the metalloid face for all studied doping types and is related to the different mobilities of the A(g) and B(g) dislocations. This behaviour is compared with a model previously developed for hardness polarity in GaAs. (Author abstract) 16 refs.

Barbot, J.F. (CNRS, Poitiers, Fr); Rivaud, G.; Desoyer, J.C. *J. Mater Sci* v 231 n 5 May 1988 p 1655-1659.

**093586 MICROHARDNESS OF (Hg, Cd)Te.** The microhardness of (Hg, Cd)Te has been investigated by means of Vickers measurements. The measured hardening effect, dependent on composition, is discussed as a function of mutual changes of the binding properties of the solid solution and, additionally, as a function of a favoured formation of (3Cd:1Hg)Te tetrahedrons. (Author abstract) 5 refs.

Schenk, M. (Humboldt-Universität zu Berlin, Berlin, East Ger); Fissel, A. *J. Cryst Growth* v 86 n 1-4 Jan 1 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 502-505.

**093587 VICKERS HARDNESS OF Hg<sub>1-x</sub>Cd<sub>x</sub>Te EPILAYERS GROWN BY ISOTHERMAL VAPOR PHASE EPITAXY.** A novel method for preparing graded compositions of Hg<sub>1-x</sub>Cd<sub>x</sub>Te epilayers is presented. The epilayers are grown by an isothermal vapor phase epitaxial technique, which uses a CdTe substrate and either Te-rich HgTe or HgCdTe as the source. The substrate is positioned vertically to the source allowing a graded composition of HgCdTe epilayer to be deposited. Epilayer thickness of 100-200 μm were deposited, with  $x$  values ranging from 0.1 to 0.7. Vickers hardness measurements were made over the composition range with hardness values ranging from 33 to 75 kg/mm<sup>2</sup>. These values are similar to hardness values in the literature which were measured on individual bulk specimens. Our method is particularly effective since a single oriented layer of varying composition is measured rather than separately prepared samples of different orientation. (Author abstract) 37 refs.

**093588 ESTIMATE OF FREE-CARRIER ABSORPTION BY PHOTON-IONIZED IMPURITY-PLASMON PROCESSES IN N-TYPE Hg<sub>1-x</sub>Cd<sub>x</sub>Te.** The infrared absorption spectra for a sample of Hg<sub>1-x</sub>Cd<sub>x</sub>Te with  $x=0.19$  reported previously have been recalculated including both the absorption due to individual carrier transition and that due to collective excitation of carriers (plasmons), taking into account the dispersion of refractive index and the non-parabolicity of the energy band in the absence of Landau damping. The agreement between theory and experiment is good and suggests that free-carrier absorption due to collective excitation can play a noticeable role in the frequency range from  $\omega_p$  up to  $2\omega_p$  and above. The value of the concentration of ionized impurities thus obtained is believed to be more accurate than that obtained previously. (Author abstract) 18 refs.

**093591 LUMINESCENCE OF MIXED ZnS-CdS SEMICONDUCTOR CATALYSTS IN NAFION POLYMER FILMS.** The luminescence of CdS and mixed ZnS-CdS semiconductor particles supported in Nafion polymer films has been studied to elucidate the previously reported synergism in the ZnS-CdS system for photoredox H<sub>2</sub> production. The luminescence of these systems is complex, depending on the history of the particular sample, the intensity and wavelength of the exciting light, and the presence of ions that can quench specific emitting states (e.g. S<sup>2-</sup> or methylviologen). For the mixed ZnS-CdS system the two semiconductors do not alloy but there is intimate contact between the ZnS and CdS phases, indicated by the complete quenching of ZnS luminescence. Prolonged irradiation produces a luminescent ZnS phase. The emission features agree reasonably well with sub-bandgap states deduced from earlier photoconductivity studies on CdS crystals. These results help explain why the reported emission features of CdS are as varied as the laboratories reporting them. (Author abstract) 26 refs.

**093592 OPTICAL NONLINEARITY OF CdS.** The discovery and investigation of optically nonlinear behav-

ior of CdS is reviewed. The development is described from nonlinear anti-Stokes excitation via the characterization of inelastic light scattering processes and the identification of high-density phenomena like biexciton creation, excitonic collisions, and electron-hole plasma generation towards very recent time-resolved gain, light-induced grating, and in particular optical bistability experiments. CdS is thus shown to allow for an extremely wide variety of different optically nonlinear processes and may be regarded as a model material for this field. Possible applications show up for several of the described phenomena. (Author abstract) 117 refs.

**093593 EXCITON-RELATED OPTICAL NONLINEARITIES IN SEMICONDUCTORS AND SEMICONDUCTOR MICROCRYSTALLITES.** We report on large optical nonlinearities due to specific many-body effects in high-density electron-hole pair systems. On bulk CdS we study the effect of free-carrier screening on the absorption and refraction in the vicinity of the band-gap at room temperature. Steady-state saturable absorption at mW-power levels and four-wave mixing with first-order efficiencies as large as 2% of the incoming light are demonstrated on a 1 μm slab. On CuBr microcrystallites embedded in glass we investigate the changes of the exciton absorption caused by many-exciton effects both at cryo and room temperature. In contrast to bulk semiconductors, we observe a blue shift of the exciton peak at resonant optical excitation. In addition, strong saturation of absorption with very large contrast shows up. We find Lorentzian saturation intensities in the 100 kW/cm<sup>2</sup> range. (Author abstract) 27 refs.

**093594 BAND EDGE ABSORPTION SATURATION DYNAMICS OF SEMICONDUCTORS.** Temporal evolution of the transmission coefficient and of the output light intensity during the laser pulse is investigated for CdSe single crystals. The nonlinear bleaching observed in the Urbach region of the absorption spectrum at room temperature has a threshold character. With the increase of the laser pulse energy exceeding the threshold value  $E_1$ , the transmission coefficient at first experiences a strong rise and then reaches a saturation. A phenomenological model describing the observed features is proposed assuming an abrupt dependence of the absorption coefficient on the photoexcitation density. The sequence of dynamical relationships between the transmission and the pump level is quantitatively analyzed. From experimental data the threshold specific energy and the specific energy required for the bleaching of a 100 μm sample are deduced. They are equal to  $2.2 \times 10^{-11}$  and  $1.9 \times 10^{-10} \text{ J}/\mu\text{m}^2$ , respectively. (Author abstract) 6 refs.

**093597 DIRECT OPTICAL TRANSITIONS IN CdGaInS<sub>4</sub>.** CdGaInS<sub>4</sub> single crystals are candidates for application as photovoltaic detectors in the ultraviolet spectral region. This note presents experimental results on the absorption edge of CdGaInS<sub>4</sub> in a wide range of the absorption coefficient at temperatures of 80, 180, and 300 K. The investigation has shown that CdGaInS<sub>4</sub> is a direct band gap semiconductor ( $E_g = 2.92$  eV at 300 K) and has an exponential density of states tail below the conduction band ( $\Delta = 60$  to 77 meV). The energy gap is close to  $E_g = 2.86$  eV. 5 Refs.

**093598 INFLUENCE OF DEFECT GENERATION PROCESS IN CdIn<sub>2</sub>S<sub>4</sub> SINGLE CRYSTALS ON THE PHOTOLUMINESCENCE AND RAMAN SCATTERING SPECTRA.** Photoluminescence (PL) and Raman scattering (RS) spectra is explained in dependence of the applied heat treatment conditions are studied. The deformation of the integral PL spectrum is explained by a model within which the local levels are due to the intrinsic defects of the semiconductor. The presence of a wide-band background in the RS spectra and the deformation of the PL spectra characteristic for samples subjected to rapid cooling after annealing at temperatures not lower than  $T_c \approx 300$  to 320 °C are the result of a phase transition of the order-disorder type. The latter occurs at  $T \approx T_c$  and causes the conversion of the crystal structure from a normal spinel ( $T < T_c$ ) into a partially inverted one ( $T > T_c \approx 320$  °C). (Edited author abstract). 18 Refs.

**093599 PLASMA REFLECTIVITY SPECTRA OF INHOMOGENEOUS Cd<sub>0.2</sub>Hg<sub>0.8</sub>Te CRYSTALS.** Results of numerical calculations and experimental studies of the influence of microinhomogeneities on plasma reflectivity spectra of ion-implanted Cd<sub>0.2</sub>Hg<sub>0.8</sub>Te crystals are presented. The calculations of plasma reflectivity spectra were performed for a model implanted crystal consisting of a uniform substrate and a disordered surface layer. Two types of microstructure of the damaged layer were considered: 1) a separate grain structure in which particles of material A are dispersed in a continuous host of material B and 2) an aggregate structure being a random mixture of two (A, B) or three (A, B, C) phases. 7 Refs.

**093600 OPTICAL PROPERTIES OF II-VI SEMI-MAGNETIC SEMICONDUCTORS.** A short review about recent optical data pertaining to band structure and energy levels related to magnetic ions in semimagnetic semiconductors (SMSC) is presented. Then, optical effects which demonstrate the strength of exchange interaction between magnetic ions and free or weakly bound carriers are considered; they include the already well studied giant magneto-optical effects and the formation of magnetic polarons (MP). Photoluminescence in large gap materials is a good way to study different aspects: bound excitons still present a low spin concentration, donor-acceptor (D-A) pair emission to study magnetic polarons bound to acceptors, with special emphasis upon the anisotropy in wurtzite structures. At higher spin concentration, proper-

ties of localized excitons have been deduced from optical pumping (site selection) and time resolved spectroscopy, on a picosecond time-scale. A few examples in the new field of SMSC based superlattices and quantum wells are also given. (Author abstract) 36 refs.

**093601 EXCITATION WAVELENGTH AND PUMP CHOPPING FREQUENCY DEPENDENCE OF PHOTOREFLECTANCE IN Hg<sub>1-x</sub>Cd<sub>x</sub>Te.** We have measured photoreflectance (PR) at 77 K in the vicinity of the E<sub>1</sub> optical feature from Hg<sub>1-x</sub>Cd<sub>x</sub>Te (0.14 < x < 0.3) using infrared (3.39 μm) and deep blue-violet (4579 and 4067 Angstrom) pump beams; both n- and p-type materials were investigated. The spectral lineshapes were fitted using existing theories of electromodulation yielding interband energies and broadening parameters. In addition, the dependence of the PR intensity on the modulation frequency (f) was studied in order to obtain information regarding surface (interface) traps. The variation of PR intensity with f yielded characteristic trap time constants in the range 1-4 ms. (Author abstract) 20 refs.

**Oxidation** See Also CATALYSTS—Cadmium Sulfide.

**093603 MECHANISM OF PLASMA OXIDATION FOR THE SURFACE OF Cd<sub>x</sub>Hg<sub>1-x</sub>Te.** The surface condition of narrow-band solid solution of Cd<sub>x</sub>Hg<sub>1-x</sub>Te determines to a marked extent the characteristics of optoelectronic instruments fabricated from it. Therefore, the passivation of its surface by creating a thin layer of intrinsic oxide on it by various methods is the objective of numerous studies. The electrochemical method of oxidation is the most common. According to recent articles on plasma oxidation of this surface, the oxides thus obtained have better and stabler characteristics than those obtained with the electrochemical method. But no investigations have been conducted on possible mechanisms for this method. In the present article we present the results of a study on the oxidizing mechanism for the surface of Cd<sub>x</sub>Hg<sub>1-x</sub>Te in an oxygen plasma and a brief characterization of the oxide-semiconductor interface. 20 refs.

**093606 NEW HIGH PRESSURE PHASE OF CdTe.** The phase transition of CdTe have been studied by high pressure x-ray diffraction with a diamond anvil cell up to 39.20 GPa at room temperature. It was found that the transformation sequences of CdTe is from zinc blende phase to NaCl phase at 3.31 GPa, to β-Sn phase at 10.33 GPa and to a new phase at 12.18 GPa. The new phase appears to have a simple orthorhombic structure (S.G.Pmm2) with two atoms in the unit cell. The positions of atoms are Cd(0, ½, ¼) and Te(0, 0, 0). The lattice parameters of the orthorhombic phase at 19.30 GPa are a = 2.8102 (Å), b = 5.2580 (Å), c = 3.0265 (Å). (Author abstract) 18 refs.

## Photoconductivity

**093608 HOT ELECTRON EFFECTS IN FREE CARRIER PHOTOCONDUCTIVITY IN HgCdTe.** The research and observation of free electron absorption and photoconductivity in N-type Hg<sub>0.78</sub>Cd<sub>0.22</sub>Te at 100k have been made using a cw tunable CO<sub>2</sub> laser. It is found that the photoexcitation gives rise to an increase in the hot electron temperature and a change of mobility. The analysis of experimental results shows that the ionized impurity scattering dominates variation of the mobility. There is a possibility to develop a new type far infrared detector. (Author abstract) (In Chinese) 10 refs.

Wang, Weili (Peking Univ, China); Xing, Qijiang. *Hong-wai Yanjiu A-JI* v 6 n 5 1987 p 341-346.

**093609 PHOTOCONDUCTIVITY OF (CdSe, ZnS):La.** Photoconductivity of rare earth doped mixed bases of II-VI compounds has not drawn any particular attention, although formation of mixed bases is important from the point of view of extending the maximum response in the visible region. With this in mind, the photoconductivity of (CdSe,ZnS):La has been investigated. The lower values of photocurrent at lower and higher concentrations of lanthanum may be due to a release of fewer electrons from lanthanum and concentration quenching, respec-

tively. Two trap depths at 0.54 and 0.45 eV have been found and these depend on the concentration of lanthanum. 4 refs.

**093610 TEMPERATURE DEPENDENT PHOTOCONDUCTIVITY AND PHOTOLUMINESCENCE OF  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$ .** Photoconductivity (PC) and Photoluminescence (PL) studies of  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$  are reported in the ranges of composition  $0.15 < x < 0.40$  and temperature  $10 < T < 300$  K. The results of this study show that p-d transitions make an important contribution to the optical properties of  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$  in the above range of compositions. Strong changes in both the PL and PC spectra are observed when the  $\Gamma_6$  conduction band edge shifts through the Mn 3d<sub>5</sub> levels. This explains the specific temperature dependence of the PC for  $x=0.32$  and the strong increase in the normalized intensity of the PL band at 2.0 eV at  $x > 0.35$ . The shift in the binding energy of the excitonic contribution to the PC with temperature agrees well with the model of Golnik on interactions of the excitons with the Mn<sup>2+</sup> spins. (Edited author abstract) 32 refs.

**Physical Properties** See Also MAGNETIC SEMICONDUCTORS—Physical Properties.

**093613 LATTICE PARAMETERS, ENERGY GAPS, AND MAGNETIC PROPERTIES OF THE  $\text{Cd}_x\text{Hg}_y\text{Mn}_z\text{Te}$  ALLOY SYSTEM.** Polycrystalline samples of  $\text{Cd}_x\text{Hg}_y\text{Mn}_z\text{Te}$  alloys ( $x+y+z=1$ ) are prepared by the standard melt and anneal technique. Debye-Scherrer powder X-ray photographs are used to determine equilibrium conditions in the alloys, to delineate the range of single phase solid solution and to determine values of zinc blende lattice parameter  $a$ . Optical absorption measurements are made to give room temperature values of energy gap  $E_g$  for the single phase alloys. Measurements of magnetic susceptibility in the temperature range 4 to 250 K are made to give values of  $T_g$ , the spin-glass transition temperature, and  $\theta$ , the Curie-Weiss temperature. Analysis of these data shows that for samples with  $g > 1.5$  ev, the results are well explained by the superexchange mechanism previously used in the analysis of the  $\text{Cd}_x\text{Zn}_y\text{Mn}_z\text{Te}$  etc. results, but that for the cases with  $E_g \leq 1.5$  ev a

Bloembergen-Rowland type of interaction needs to be included in order to explain the experimental values of  $T_g$  and  $\theta$ . (Edited author abstract) 21 refs.

**093614 WAVELENGTH AND TEMPERATURE DEPENDENCE OF THE FARADAY EFFECT IN  $\text{Cd}(1-x)\text{Mn}(x)\text{Te}$ .** The wavelength dependence of the Faraday effect at fixed temperature and the temperature dependence at fixed wavelength have been measured in  $\text{Cd}(0.55)\text{Mn}(0.45)\text{Te}$ . These results can be explained using a simple exciton model and the known temperature dependence of the magnetic susceptibility and exciton energy. (Edited author abstract) 13 refs.

Butler, M.A. (Sandia Natl Lab, Albuquerque, NM, USA). *Solid State Commun* v 62 n 1 Apr 1987 p 45-47.

**093615 DAMAGE STUDY AND PHYSICAL PROPERTIES OF ION IMPLANTED  $\text{Cd}_{0.7}\text{Hg}_{0.3}\text{Te}$  PROCESSED BY FURNACE AND RAPID THERMAL ANNEALING.** Ion implantation of In, Ar and Xe was carried out on p-type  $\text{Cd}_x\text{Hg}_{1-x}\text{Te}$  ( $x = 0.7$ ) and followed by both furnace annealing (FA) in the presence of Hg vapour and rapid thermal (RTA) on encapsulated crystals. Rutherford backscattering spectroscopy and photoluminescence experiments show that the implantation damage is removed by FA at 400°C for 1 h or RTA at 380°C for 10 s. The In-implanted profile obtained by SIMS exhibits a diffusion broadening following FA, while the In atomic distribution is very little affected by RTA. Sheet Hall-effect measurements indicate that following FA at 300 and 400°C electron conductivity appears and is associated with some activation of the In and with implantation-induced defects. RTA, which removes the defects very well, does not lead to any n-type conversion that could be related to the absence of a Hg external phase. (Author abstract) 15 refs.

## Plasmas

**093616 PICOSECOND PLASMA DYNAMICS AND ALL-OPTICAL DATA PROCESSING.** Using time resolved pulse and probe spectroscopy, the transmission modulation of CdSe platelets is investigated under excitation and generation of a dense electron-hole plasma. Induced absorption is related to exciton screening, band-gap renormalization, and energy relaxation in a high density electron-hole plasma. These investigations also are of interest from the point of view of optical signal processing because an all-optical picosecond inverter gate and more generally a many input NOR gate can be built based on the induced absorption which occurs in the presence of a dense electron-hole plasma. The operation of such a device is described and discussed in relation with the possible development of optical coprocessors (compatible with a parallel processing of data) and especially in relation with the critical problem of associating and cascading optical NOR gates. (Edited author abstract) 25 refs.

## Pressure Effects

**093617 PRESSURE DEPENDENCE OF THE BOWING PARAMETER OF DIRECT BAND GAP OF  $\text{CdSe}_x\text{Te}_{1-x}$ .** The variation of the lowest direct band gap of compounds  $\text{CdSe}_x\text{Te}_{1-x}$  with hydrostatic pressure has been measured by photoluminescence at room temperature. This allowed determination of pressure dependence of the bowing parameter. Our data compared to theoretical calculations based on the dielectric model indicates that the average ionic potential is constant with pressure.

This result has been previously assumed in the calculation of energy-band pressure coefficients and proved fundamental for the agreement with experimental values for a wide variety of semiconductors. (Author abstract) 12 refs.

**093622 STUDY OF THE FUNDAMENTAL ABSORPTION EDGE OF  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$ .** The measurements of the fundamental absorption edge in  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$  for  $x=0.007, 0.20, 0.30, 0.45$  in the temperature range 10 to 300 K by transmission are reported and discussed. It is shown that the variation of energy gap with temperature is linear, and the temperature coefficient of the energy gap

is negative and strongly depends on the composition of the  $\text{Cd}_{1-x}\text{Mn}_x\text{Te}$  mixed crystals. (Author abstract) In Chinese. 4 refs.

**093623 DEEP LEVEL STRUCTURE AND COMPENSATION MECHANISM IN IN-DOPED CdTe CRYSTALS.** Deep Level Transient Spectroscopy (DLTS) and Optical Deep Level Transient Spectroscopy (ODLTS) experiments have been conducted on a series of In-doped CdTe crystals grown by the Bridgman or the travelling heater (ThM) methods using Te as the solvent. The THM samples are n-type but strongly compensated. Annealing at 700°C under high Cd vapor pressure leads to a decompensation of the crystals. The electron concentration is then a measure of the donor (In) concentration, which was in the range  $3 \times 10^{16}$ – $1.5 \times 10^{18} \text{ cm}^{-3}$ . Six and eight electron traps are, respectively detected in the non-annealed and annealed samples at a concentration level  $10^2$ – $10^3$  times below the net electron concentration. They cover the energy range 0.2–0.8 eV. Similar traps are found in both types of crystals, the concentration of which increases with In content and after annealing. (Edited author abstract) 30 refs.

**093624 PICOSECOND TIME-RESOLVED LUMINESCENCE OF LOCALIZED EXCITONS IN  $\text{CdS}_{1-x}\text{Se}_x$ .** We present time-resolved luminescence results on  $\text{CdS}_{0.3}\text{Se}_{0.64}$  which give a new insight on the kinetics of excitons localized by alloy potential fluctuations. By exciting in the localized exciton band with detection close to the exciting wavelength we obtain the lifetime across the band. Below the exciting laser energy two processes contribute to luminescence: transfer of localized excitons by tunnel effect assisted by acoustical phonons, and luminescence (assisted by acoustical phonons) of all the states excited at time  $t=0$  either directly or through their acoustical absorption wing. The time behavior of luminescence with respect to the detuning from the exciting energy helps to discriminate between those two contributions. Furthermore it shows that intermediate long-living states are involved in the exciton relaxation process. (Author abstract) 13 refs.

Gourdon, C. (Univ Paris VII, Paris, Fr); Lavallard, P.; Permogorov, S.; Reznitsky, A.; Aaviksoo, Y.; Lippmaa, Y. *J Lumin* v 39 n 2 Dec II 1987 p 111-116.

**093625 COMPOSITIONAL DEPENDENCE OF INFRARED PHONON PARAMETERS FOR  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ .** The full set of Lorentzian oscillator parameters describing the two-mode phonon behavior in  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  is reported. A new analysis of reflectivity spectra combined with existing results gives the most accurate available values for the CdTe-like and HgTe-like transverse optical frequency, strength and (for the first time) damping constant vs CdTe fraction  $x$  at room, liquid nitrogen and liquid helium temperatures. Polynomial fits vs  $x$  for each parameter are provided for use in characterizing  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  and the HgTe-CdTe superlattice. (Author abstract) 26 refs.

**093626 MAGNETO-OPTICAL SPECTROSCOPY OF DONOR BOUND ELECTRONS IN  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ : VOIGT AND FARADAY GEOMETRY.** We report the observation of the Voigt geometry impurity transition ( $|000+\rangle \rightarrow |101+\rangle$ ) in n-type  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  ( $x=0.237$  and  $x=0.270$ ). The transition energies agree with the non-parabolic theory of hydrogenic donors when central cell effects are included. Measurements of the Faraday geometry ( $|000+\rangle \rightarrow |110+\rangle$ ) transition are also reported. This work provides evidence for the condensation of electrons onto ionized donors in magnetic fields above the Mott-Anderson metal-insulator transition in  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ . (Edited author abstract) 16 refs.

**093627 PICOSECOND LUMINESCENCE OF EXCITONS LOCALIZED BY DISORDER IN  $\text{CdS}_x\text{Se}_{1-x}$ .** We have investigated in  $\text{CdS}_x\text{Se}_{1-x}$  and in pure CdSe the temporal evolution of the excitonic luminescence with 20 ps time resolution. In CdSe and in alloys with  $x < 0.15$  the onset and decay of the luminescence can be described by time constants which are independent of the photon energy in the region of the free and bound excitons. In contrast, the time constants vary strongly over the main emission band for  $x > 0.15$ , which is attributed to the relaxation of excitons localized by compositional disorder. A simplified hopping model is presented which accounts for the experimental findings. (Author abstract) 24 refs.

Shevel, S. (Philipps-Univ Marburg, Marburg, West Ger); Fischer, R.; Goebel, E.O.; Noll, G.; Thomas, P.; Klingshirn, C. *J Lumin* v 37 n 1 Apr 1987 p 45-50.

**093628 THERMAL IONISATION AND PHOTOIONISATION PROPERTIES OF DEEP TRAPS IN N TYPE CdTe.** Physical properties of some native deep electron traps in n type CdTe have been investigated by means of capacitance techniques. Using D.L.T.S. measurements, 4 levels labelled  $E_1$  to  $E_4$  have been detected with apparent ionisation energies in the range of 0.24–0.88 eV and unusually small electron capture cross sections  $\sigma_c \approx 10^{-20} \text{ cm}^2$ . Deep Level Optical Spectroscopy (D.L.O.S.) has been used to measure the spectral dependence of the photoionisation cross section of the defects. Interpretation is made in terms of one dimensional configuration coordinate diagrams. From these, it is concluded that levels  $E_2$   $E_3$   $E_4$  are weakly relaxed while level  $E_1$  is strongly coupled to the lattice. (Edited author abstract) 10 Refs.

Debbag, F. (CNRS, Montpellier, France); Bastide, G.; Rouzeyre, M. *Solid State Commun* v 67 n 1 Jul 1988 p 1-5.

**093629 RAMAN SCATTERING IN  $\text{Cd}_{1-x}\text{Mn}_x\text{Se}$  UNDER HYDROSTATIC PRESSURE.** The behaviour of phonons in the mixed crystals  $\text{Cd}_{1-x}\text{Mn}_x\text{Se}$  ( $0 \leq x \leq 0.45$ ) in the wurtzite phase is investigated by Raman scattering under hydrostatic pressure. The measurements are reported while increasing as well as decreasing the pressure. Mixed crystals of all the compositions as well as pure CdSe undergo a phase transition to NaCl structure between 22 and 29 kbar depending on the composition. The reverse transitions occur at much lower pressures indicating hysteresis. In mixed crystals with  $x \geq 0.40$ , a new Raman peak appears under hydrostatic pressure which lies between CdSe-like longitudinal optical (LO) phonon and MnSe-like transverse optical (TO) phonon. The new mode behaves in a manner similar to other zone-center optical phonons and continues to exist even when the pressure is fully released after cycling through the phase transition. Zone-boundary acoustic phonons are found to exhibit softening. (Author abstract) 21 Refs.

**093630 PHOTOACOUSTIC SPECTROSCOPY OF CdTe AND (Hg, Cd)Te.** The photoacoustic (PA) spectroscopy using a piezoelectric PZT transducer attached to the sample is shown to be successfully employable also for small gap II-VI semiconductor bulk crystals and epilayers both in the low- and high-absorption region. The PA measurements of CdTe and (Hg, Cd)Te mixed crystals carried out at room temperature yield information about the quality and composition of the samples, respectively. Especially, the PA spectroscopy can be used to study the exciton absorption region of a layer also in the case of a substrate with smaller energy gap, as demonstrated for CdTe epilayers on GaAs as an example. **093631 SPATIAL ORIGIN OF VARIOUS PL LINES IN CdTe AT 77 K.** We report on the spatial origin of the exciton and defect photoluminescence lines in CdTe at 77 K. A scanning electron microscope was used to obtain images of cathodoluminescence that was spectrally resolved with the help of optical filters. We observe that the exciton and the defect luminescence lines originate from different spatial locations on the sample. The exciton line itself appears to originate from two different locations, one of which is clustered dislocations. These results question the validity of the generally accepted criterion that a large ratio of exciton to defect emission in the luminescence spectrum of CdTe at 77 K implies good crystal quality. (Author abstract) 8 refs.

**093632 PHOTOLUMINESCENCE SPECTROSCOPY OF EXCITONS FOR EVALUATION OF HIGH-QUALITY CdTe CRYSTALS.** Near band-edge photoluminescence spectra are presented for a variety of CdTe samples. The relationship between sample quality and exciton emission spectra is discussed. Time-resolved spectroscopy, excitation spectroscopy, and power-dependence of photoluminescence are reported. The change in exciton photoluminescence power dependence with excitation wavelength indicates that the superlinear power dependence is due to the formation of excitons from photoexcited electrons and holes. (Author abstract) 13 refs.

**093639 OPTICAL NONLINEARITY DUE TO INCREASED ABSORPTION IN CdS AT ROOM TEMPERATURE.** In this paper two types of optical nonlinearity in CdS crystal platelets due to the increased absorption with increasing incident intensity at room temperature (RT) are reported. The experiments reveal their origin. One is ascribed to the effect of lattice heating in the transmission of a laser tuned around the exciton in CdS. The other is ascribed to the absorption band of exciton-electron (Ex-EI) scattering moving towards the low energy direction under high excitation. 2 refs.

**093647 LOCAL AND QUASI-LOCAL MODES OF Zn IN CdTe.** The far infrared absorption and reflection spectra of the mixed crystals  $Zn_xCd_{1-x}Te$  with small x in the temperature range of 4.2-300K and the frequency region of  $20-350 cm^{-1}$  are reported. The local and quasi-local modes induced by Zn and ZnTe in CdTe and the CdTe-like 2TA two-phonon absorption are observed for the first time. The frequencies of the modes are estimated by use of the mass-defect model combined with Green's function method. The random element-isodisplacement (REI) model is used to calculate the two-mode-behaviors of the mixed crystals and to fit the reflection spectra. Besides, the temperature dependence of the phonon absorption is calculated and well explained. (Author abstract) 5 refs.

## Surfaces

**093648 STUDY ON WORK FUNCTION OF THE {0001} FACES OF CdS CRYSTAL - III. EFFECT OF THE IRRADIATION WITH RED LIGHT.** By means of a highly sensitive thermistor (sensitivity:  $10^{-3}^\circ C$ ) as well as a Kelvin electrode of NESA glass with a detection sensitivity of several mv, the contact potential difference and the temperature of a crystal were measured with respect to CdS polar surfaces. It was confirmed that when a photoconducting crystal is irradiated at room temperature by weak light with bulk excitation for a certain time and then interrupted, the temperature drop and rapid decrease in the electric conductivity of the crystal causes a pyroelectric charge on the polar surface. (Edited author abstract) 5 refs.

Sasaki, Kazuo (Hiroaki Univ, Hiroaki, Jpn). *Jpn J Appl Phys Part 1* v 26 n 9 Sep 1987 p 1467-1469.

**093649 CORRELATION OF FERMI LEVEL SHIFT WITH PHOTOVOLTAGES AT RUTHENIUM-MODIFIED CdTe SURFACES.** The effect of ruthenium surface modification is shown to considerably improve the properties of CdTe-based photoelectrochemical (PEC) solar cells. Contact potential difference (CPD) measurements on n- and p-CdTe show shifts in surface Fermi level in opposite directions corresponding to an increase in barrier height in each case. The magnitudes of

the changes in CPD are approximately equal to the increase of open-circuit voltage,  $V_{oc}$ , observed in photoelectrochemical cells. (Author abstract) 10 refs.

Mandal, K.C. (Jadavpur Univ, Calcutta, India); Basu, S.; Bose, D.N. *CHEMTECH* v 17 n 8 Aug 1987 p 559-561.

**093650 SURFACE PHOTOVOLTAGE SPECTROSCOPY FOR REAL N- AND P-TYPE (110) CdTe SURFACES IN THE VISIBLE AND NEAR INFRA-RED SPECTRAL RANGE.** Surface photovoltage spectroscopy has been carried out on real n- and p-type (110) CdTe surfaces in the wavelength range 0.36-1  $\mu$ m at room temperature (300 K), and at atmospheric pressure. The measurements show the existence of surface states at 1.3; 1.48, and 1.2; 1.46 eV within the energy gap of n- and p-type CdTe, respectively. Surface states greater than the energy gap at 2.24, 2.38, 2.68, and 3.1 eV have also been detected in n-type samples and at 1.66, 2.12, 2.69 eV in p-type samples. (Author abstract) 14 refs.

El-Dessouki, M.S. (Cairo Univ, Giza, Egypt); Attia, V.A. *Appl Phys A* v A45 n 2 Feb 1988 p 175-178.

**093651 SURFACE DERIVATIZATION AND ISOLATION OF SEMICONDUCTOR CLUSTER MOLECULES.** The authors describe a synthesis of nanometer-sized clusters of CdSe using organometallic reagents in inverse micellar solution and chemical modification of the surface of these cluster compounds. In particular we show how the clusters grow in the presence of added reagents and how the surface may be terminated and passivated by the addition of organoselenides. Passivation of the surface allows for the removal of the cluster molecules from the reaction medium and the isolation of organometallic molecules which are zinc blende CdSe clusters terminated by covalently attached organic ligands. Preliminary cluster characterization via resonance Raman, infrared, and NMR spectroscopy, X-ray diffraction, transmission electron microscopy, and size-exclusion chromatography is reported. (Author abstract) 10 refs.

**093653 EVIDENCE FOR ADDUCT FORMATION AT THE SEMICONDUCTOR-GAS INTERFACE, PHOTOLUMINESCENT PROPERTIES OF CADMIUM SELENIDE IN THE PRESENCE OF AIMES.** The authors demonstrate that bulk PL from etched or cleaved n-CdSe single crystals is strongly affected by exposing the crystals to a family of gaseous amines. Moreover, the magnitude of the interaction can be correlated with the intrinsic basicity of the amines, thereby evidencing adduct formation with the surface. For etched samples, the PL data are in good agreement with the dead-layer model; cleaved samples exhibit PL properties that do not fit the dead-layer model, indicating that the PL changes arise, at least in part, from changes in surface recombination velocity. We also show that PL changes can be used to construct Langmuir adsorption isotherms. It is also shown that exposure of etched n-CdSe substrates to other volatile classes of compounds can be used to probe the nature of the interactions that perturb the PL (photoluminescence) response. 16 Refs.

**093654 SURFACE RECOMBINATION VELOCITY MEASUREMENTS OF CdS SINGLE CRYSTALS IMMersed IN ELECTROLYTES. A PICOSECOND PHOTOLUMINESCENCE STUDY.** The effect of solution composition and concentration on the luminescence decay profile is measured for CdS single crystals immersed in various aqueous solutions. The surface recombination velocity is strongly dependent on the ionic solution composition and concentration. The experimental data are explained in terms of the chemisorption of ions on the CdS surface. (Author abstract). 22 Refs.

**093655 PREPARATION OF STOICHIOMETRIC MERCURY CADMIUM TELLURIDE SURFACES.** A technique involving cathodization of an anodized surface has been proposed as a surface treatment of mercury cadmium telluride substrates in the fabrication of infrared-sensitive devices. The resultant surface was analyzed with X-ray photoelectron spectroscopy and compared with surfaces produced by cleavage, sputtering, and chemical etching. It was found that the cathodized surface had a surface composition close to the bulk stoichiometry. The first monolayer of the surface was enriched in mercury and depleted in cadmium. This surface was also more inert towards air oxidation than the Br-methanol treated surface, probably because of the surface enrichment of mercury. (Author abstract) 8 refs.

**093657 SYNTHESIS OF CADMIUM SULFIDE IN SITU IN REVERSE MICELLES AND IN HYDROCARBON GELS.** The synthesis in situ of cadmium sulfide semiconductors in AOT reverse micelles produces smaller and more monodispersed particles than are obtained in Triton reverse micelles or in aqueous solution. When gelatine is added to the previous solution, the semiconductor is entrapped in a hydrocarbon gel and its size remains the same as that obtained in reverse micelles. The size of the sulfide cadmium aggregate formed in AOT hydrocarbon gels is similar to that obtained under similar conditions in AOT reverse micelles. AOT surfactant can play the role of stabilizing agent. However, a more efficient stabilization is obtained by adding to AOT reverse micelles another stabilizing agent such as sodium hexametaphosphate. (Edited author abstract) 27 refs.

**093658 THERMODYNAMIC MODEL OF THE GAS TRANSPORT IN A HWE SYSTEM.** A thermodynamic consideration is given of the gas transport in a hot wall epitaxy (HWE) system which involves a compound AB dissociating completely in the gas phase. Evaporation, transport, and kinetic limited regimes can occur in HWE. Only the transport limited mode is considered in this paper. HWE is a half-open epitaxy method permitting a gas flow of dissipation through a defined hole on the locus of the substrate. The results of the computations are discussed with respect to CdTe. (Edited author abstract) 11 refs.

**Thick Films**

**093659 BURSTEIN EFFECT IN THICK FILMS OF CADMIUM ORTHOSTANNATE (Cd<sub>2</sub>SnO<sub>4</sub>).** The shift in the fundamental optical absorption edge towards higher energy accompanied by a large increase in electrical conductivity and with higher band gap in a semiconductor is termed the 'Burstein Effect'. This letter deals with the shift observed in the optical absorption edge for doped and undoped thick films of Cd<sub>2</sub>SnO<sub>4</sub>. In the case of doped films, the optical absorption edge shifts from 534 to 514 nm, the band gap increases from 2.32 to 2.41 eV and the reflectance decreases from 40 to 20% on going from highly resistive (645 k $\Omega$ ) samples. For the undoped films, the shift is from 528 to 520 nm, the band gap increases from 2.35 to 2.36 eV and the reflectance decreases from 41.5 to 39.5% as the resistance of the sample increases from 10<sup>5</sup> to 10<sup>3</sup> $\Omega$ . 12 refs.

**093660 CRYSTALLINE PROPERTIES OF INDOPEDED CdS THIN FILMS.** Polycrystalline indium-doped CdS thin films have been deposited onto glass by vacuum evaporation from two crucibles of CdS and indium. The influence of the indium concentration and the substrate temperature on the morphology and the crystalline properties of the films have been studied. The films crystallize in the hexagonal phase and show a columnar structure perpendicular to the substrate. The grain size increases with the substrate temperature and with the indium concentration. The interplanar spacing between the (002)H planes also increases with the indium concentration, but, when it is higher than  $7 \times 10^{19}$  cm<sup>-3</sup>, indium agglomerates appear in the films. A decrease of the grain size and (002)H interplanar spacing results with further increases in indium concentration. (Author abstract) 23 refs.

**093661 VAPOUR-DEPOSITED CdS FILMS AND THEIR DEPENDENCE ON THE SOURCE MATERIAL.** An investigation has been made of the conditions required for the formation of vapor-deposited CdS thin films with reproducible characteristics suitable for use in photovoltaic solar cells. Cathodoluminescence spectroscopy has been used to provide information on differences in composition between the deposited films and the source material from which they were produced, and particular consideration has been given to the influence of the source

material structure and stoichiometry on the electrical properties of the resultant films. Under identical deposition conditions, four different high-purity sources were shown to produce films with very different electrical characteristics, but by selecting appropriate deposition conditions (substrate temperature and deposition rate) it was found that each material was capable of generating films with the required characteristics. (Author abstract) 11 refs.

**093663 IN DOPING IN CdTe FILM BY Co-EVAPORATION OF CdTe AND In.** High-dark-conductivity CdTe films have been prepared by co-evaporation of CdTe and In. The conductivity of the films prepared in this study ranged from  $10^{-8}$  to  $10^3 \text{ Scm}^{-1}$ . The film structure was of zinc-blend type with a preferential orientation of the (111) planes parallel to the substrate. Analyzing the film structure by X-ray analysis, it was found that the In atoms were doped substitutionally into the CdTe during the low-concentration doping stage and then doped interstitially during the high-concentration doping stage. The properties of a very-high-conductivity film could be explained by adopting a new periodicity concept of the doped film using a tentative model. (Author abstract) 12 refs.

**093664 OPTO-ELECTRONIC CHARACTERISTICS OF CHEMICALLY DEPOSITED CADMIUM SULPHIDE THIN FILMS.** Cadmium sulfide thin films showing photo-to-dark conductivity ratio up to  $10^9$  and photoconductivity up to  $3 \Omega^{-1} \text{ cm}^{-1}$  for white illumination approximately  $300 \text{ W m}^{-2}$  can be prepared from chemical baths containing thiourea and triethanolamine complex of cadmium ions. The photocurrent decay time depends on the bath temperature and the duration of storage and it ranges from a few seconds to  $10^4 \text{ s}$  per decade. The optical transmission of the films also varies significantly: from about 10% to 70-80% (above the band-gap absorption), depending on the deposition conditions. The high activation energy  $\approx 1 \text{ eV}$  for dark conductivity as well as the high photosensitivity suggest the nearly stoichiometric nature of the films. The implications of these characteristics in various opto-electronic applications are discussed. (Author abstract) 48 refs.

**093666 EFFECT OF SINTERING CONDITIONS ON THE MICROSTRUCTURE AND OPTICAL PROPERTIES OF  $\text{Cd}_{1-x}\text{Zn}_x\text{S}$  FILMS.** Polycrystalline  $\text{Cd}_{1-x}\text{Zn}_x\text{S}$  films were prepared by coating  $(1-x)\text{CdS} + x\text{ZnS}$  slurry on amorphous glass substrates and sintering in nitrogen or nitrogen atmosphere containing  $\text{ZnCl}_2$  vapor to produce films with properties suitable for fabricating all polycrystalline  $\text{Cd}_{1-x}\text{Zn}_x\text{S}/\text{CdTe}$  heterojunction solar cells. The microstructure and optical properties of these films has been correlated with composition,  $\text{CdCl}_2$  which was added as a sintering aid, sintering temperature and atmosphere. By optimizing the preparation conditions, it is possible to produce sintered  $\text{Cd}_{1-x}\text{Zn}_x\text{S}$  films on glass substrate with electrical resistivity less than  $1 \Omega \cdot \text{cm}$  and 15% higher optical transmission than CdS films. (Author abstract) 13 refs.

**093671 OPTICAL AND STRUCTURAL PROPERTIES OF POLYCRYSTALLINE CdSe DEPOSITED ON TITANIUM SUBSTRATES.** We report studies of photoluminescence, Raman scattering and x-ray diffraction performed on CdSe polycrystalline films deposited on titanium substrates by two different methods: chemical deposition and electroplating. We discuss the changes observed in these films as they are subjected to heat treatments. The differences observed in the energy gap of both types of film and their evolution as a function of annealing temperature are tentatively explained in terms of quantum confinement produced by the small grain size of the films. (Author abstract) 25 refs.

Cerdeira, F. (UNICAMP, Campinas, Braz); Torriani, I.; Motisuke, P.; Lemos, V.; Decker, F. *Appl Phys A* v A46 n 2 Jun 1988 p 107-112.

**093672 EFFECT OF BATH TEMPERATURE ON THE OPTOELECTRONIC CHARACTERISTICS OF CHEMICALLY DEPOSITED CAS THIN FILMS.** The temperature of the chemical bath used in the electrodeless deposition of cadmium sulfide thin films has been found to affect the deposition rate, optical transmission T(percentage), film morphology, photoconductivity  $\sigma_{ph}$ , photoconductivity to dark conductivity ratio  $\sigma_{ph}/\sigma_d$  and photocurrent decay time  $\tau_{ph}$ . The results pertain to CdS films deposited from aqueous chemical baths containing a triethanolamine complex of  $\text{Cd}^{2+}$  ions and thiourea, in which  $\text{Cd}^{2+}$  and thiourea were mixed in 1:0.5 and 1:0.25 molar ratios. As the bath temperature was raised from 30 to 85°C, the time required to deposit a thin film, of about 0.5  $\mu\text{m}$  thickness, from the 1:0.5 bath was reduced from 480 to 18 min and that from the 1:0.25 bath was reduced from 1320 to 25 min. Systematic variations in the optoelectronic characteristics were also observed as functions of bath temperature. (Edited author abstract). 28 Refs.

**093673 PREPARATION, ELECTRICAL PROPERTIES AND OPTICAL CHARACTERIZATION OF  $\text{Cd}_2\text{SnO}_4$  AND  $\text{CdIn}_2\text{O}_4$  THIN FILMS AS TRANSPARENT AND CONDUCTIVE COATINGS.** Transparent and conductive  $\text{Cd}_2\text{SnO}_4$  and  $\text{CdIn}_2\text{O}_4$  thin films have been prepared by reactive sputtering from Cd-Sn and Cd-In alloy targets in an  $\text{Ar}+\text{O}_2$  atmosphere. Electrical conductivities of the order of  $10^5 \Omega^{-1} \text{ m}^{-1}$  with the optical transmission as high as 90% were easily attained. Hall and thermoelectric power measurements indicate that charged point defects are responsible for the scattering of conduction indicate that charged point defects are responsible for the scattering of conduction electrons. The optical constants of the films were computed from the transmission and reflection measurements in the visible and near-IR spectral ranges using a special procedure based on a model of an inhomogeneous film with a rough surface. (Author abstract) 18 refs.

**093674 LUMINESCENCE AND PARTICLE SIZE IN MICROCRYSTALLINE CdTe THIN FILMS.** The structure of as-grown and thermally annealed microcrystalline CdTe thin films, prepared by a hot wall close-spaced vapor transport technique, has been analyzed by photoluminescence, and the results compared with those obtained with several other techniques. We found that, among all the techniques used to examine the crystalline quality of the CdTe films, photoluminescence is the most sensitive to the presence of generic defects. Heat treatment increases the average particle size from 500 Angstrom in the as-grown sample to 10000 Angstrom

after annealing at 550°C for 1 h. Nevertheless, the changes observed in the photoluminescence due to annealing can be accounted for, not in the basis of a microcrystalline particle size, but in terms of the average distance between defects. (Author abstract) 12 refs.

**093675 MICROCRYSTALLINE GRAIN SIZE GROWTH IN  $\text{Cd}_{0.95}\text{Fe}_{0.05}\text{Te}$  THIN FILMS.** In this work we have studied the growth of the microcrystalline grains in  $\text{Cd}_{0.95}\text{Fe}_{0.05}\text{Te}$  thin films, with mixed phases of amorphous and polycrystalline material, as a function of isochronal thermal annealing at different temperatures. We have found that for annealing temperatures  $T_a$  near 300°C, crystallization of the film amorphous phase takes place. The dependence of the room-temperature resistivity and thermal activation energy on the annealing temperature has also been studied and explained in terms of a model that includes grain growth and crystallization of the amorphous phase. 17 refs.

**093676 HIGH MAGNETIC FIELD CHARACTERIZATION OF (Hg, Cd)Te SURFACE LAYERS.** A description is given of the use of the Shubnikov-De Haas effect, parallel-field magnetoresistance and cyclotron resonance to give a rather complete characterisation of (Hg, Cd)Te surface accumulation layers. The Shubnikov-De Haas and parallel-field magnetoresistance enable one to distinguish the separate contributions to conductivity from surface layers and bulk, the measure surface carrier densities and very accurately deduce the number of populated subbands. The structures studied are infra-red detector elements passivated with an anodic oxide. We have found that the oxide is sensitive to above band gap UV (approximately 3.3 eV) illumination, which causes a persistent discharge of the oxide surface states below 77 K. This allows us continuously to decrease the surface carrier concentration and make accurate studies of the systematic surface charge density dependence of the subband populations, effective masses and resistance. (Edited author abstract) 29 refs.

Nicholas, R.J. (Clarendon Lab, Oxford, Engl); Nasir, F.; Singleton, J. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 656-666.

**093677 POLYCRYSTALLINE CdSe FILMS FOR THIN FILM TRANSISTORS.** In this paper X-ray, ESCA, TEM and electrical measurements on evaporated CdSe films, used in thin films transistors (TFT), are reported. Special attention has been paid to semiconductor films obtained from recrystallized mixtures of CdSe and 1-2%  $\text{In}_2\text{Se}_3$ . Such films might be represented as  $(3\text{CdSe})_x(\text{In}_2\text{Se}_3)_{1-x}$ . Doping the CdSe evaporation source with In yields 20  $\mu\text{m}$  self-aligned TFTs with excellent characteristics: electron mobility in the evaporated thin films increases from 20-50  $\text{cm}^2/\text{V}\cdot\text{s}$  for undoped films to more than 100  $\text{cm}^2/\text{V}\cdot\text{s}$  for doped films. DC stability behaviour is also improved: the TFT current drop after 180 s is reduced from 30% to less than 5%. (Author abstract) 9 refs.

**093678 ION-ASSISTED SPUTTER DEPOSITION OF CdTe LAYERS.** Epitaxial, single-phase CdTe layers

have been deposited on a variety of single-crystal substrates, including freshly cleaved KBr and NaCl and polished  $\text{BaF}_2$ , by ion-assisted, planar, rf magnetron sputtering. The substrate temperature and bias were used as independent, operator-controlled process parameters to greatly enhance the degree of orientation in the films and (or) modify the crystallographic form of the deposited layer. Thus, depending primarily on the substrate temperature and bias, the deposited CdTe films exhibited one of four forms. Compositional analysis revealed no impurities. However, films of all crystallographic phases contained a large density of planar defects such as twins, stacking faults, and low-angle grain boundaries. (Edited author abstract) 8 refs.

Das, S.R. (Nat'l Research Council of Canada, Ottawa, Ont, Can); Rajan, K.; van der Meer, P.; Cook, J.G. *Can J Phys* v 65 n 8 Aug 1987, Third Can Semicond Technol Conf, Ottawa, Ont, Can p 864-867.

**093679 TRANSMISSION ELECTRON MICROSCOPY CHARACTERIZATION OF THE MICROSTRUCTURE OF  $\text{Cd}_3\text{As}_2$  FILMS PREPARED BY PULSED-LASER EVAPORATION.** Transmission electron microscopy with an analytical X-ray system has been used to investigate  $\text{Cd}_3\text{As}_2$  films prepared by pulsed-laser evaporation. The films were deposited on amorphous substrates at approximately 120°C. They consisted mainly of a fine polycrystalline array. The crystal structure was identified as the body-centered tetragonal form of  $\text{Cd}_3\text{As}_2$ . No other crystallographic phase of  $\text{Cd}_3\text{As}_2$  was observed. Some regions with amorphous or eutectic inclusions were also observed. These results have been correlated with the electrical properties of pulsed-laser evaporated  $\text{Cd}_3\text{As}_2$  films. (Author abstract) 9 refs.

**093680 DEVICE-ORIENTED STUDY OF CdS FILMS DEPOSITED BY A HOT-WALL TECHNIQUE.** A device-oriented study was carried out on thick CdS films (25-30  $\mu\text{m}$ ) suitable for solar-cell applications deposited on glass substrates, using a hot-wall technique at a pressure of  $1 \times 10^{-6}$  Torr (1 Torr = 133 Pa). Films were characterized using X-ray diffraction, scanning electron microscopy, and transmission electron microscopy. The degree of preferred orientation was observed using a simplified version of the Schulz method. Films grown under nominally identical conditions showed two types of growth habit. Front-wall  $\text{Cu}_2\text{S}$ -CdS heterojunctions were made using a hot CuCl dip. Current-voltage characteristics were measured at room temperature. Without optimizing the cell design, open-circuit voltages of 0.45 V and short-circuit currents of 20-30  $\text{mA}\cdot\text{cm}^{-2}$  under AM2 illuminations were observed. (Edited author abstract) 16 refs.

## Vapor Deposition

**093681 PHOTO-SELECTED II-VI CRYSTAL GROWTH: A STUDY OF LOW TEMPERATURE EPITAXY.** In this paper the limitations to low temperature growth rates of HgTe and CdTe will be considered and in particular the causes of low growth rates below 200°C will be discussed. Epitaxial quality is a particular concern for high performance infrared detectors and has to be carefully characterized for layers grown at low temperatures. Previous reports of photo-MOVPE layers have used single crystal diffraction and TEM (transmission electron microscopy) to assess the crystalline quality of these layers. In this paper more detailed X-ray diffraction assessment is used to examine epitaxial layer quality. 21 refs.

Barnett, S.J. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 188-197.

**093682 OMVPE GROWTH OF CdTe-ZnTe SUPERLATTICES.** Superlattices consisting of CdTe and ZnTe have been grown using atmospheric pressure OMVPE. Structural characterization by X-ray diffraction and transmission electron microscopy along with optical characterization using photoluminescence and photoreflectance has been completed. Exceptionally bright luminescence emission compared to the corresponding alloys is observed, indicating the excellent optical quality of these layers. Similarly, in photoreflectance, we are able to observe several confined states, confirming the presence of the superlattice. Structurally, the layers exhibit a high density of defects, presumably due to the relatively large lattice and thermal expansion mismatch between CdTe, ZnTe and the GaAs substrate. (Author abstract) 19 refs.

**093683 EXTRINSIC DOPED n- AND p-TYPE CdTe LAYERS GROWN BY ORGANOMETALLIC VAPOR PHASE EPITAXY.** In this paper we report on the extrinsic n- and p-doping of CdTe layers, grown by organometallic vapor phase epitaxy. Triethylindium and arsine gas were used as n- and p-type dopants respectively, with doping levels of around  $10^{17} \text{ cm}^{-3}$  in both cases. Layers were grown on both semi-insulating CdTe and GaAs substrates. Layers grown on semi-insulating GaAs had an intervening 1-2  $\mu\text{m}$  undoped CdTe layer to relieve the strain caused by the large (14.6%) lattice mismatch of the CdTe-GaAs combination. Van der Pauw measurements were made to evaluate the quality of these layers, and mobility values as high as 3600  $\text{cm}^2/\text{V}\cdot\text{s}$  obtained at 40 K for lightly doped n-type samples. Grown junctions, made using extrinsic doped layers, have resulted in diodes with excellent electrical characteristics. (Author abstract) 11 refs.

**093684 MATERIAL CHARACTERISTICS OF  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  GROWN BY ORGANOMETALLIC VAPOR PHASE EPITAXY.** We compare the material properties of  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  grown by conventional organometallic vapor phase epitaxy (OMVPE) with those obtained by interdiffused multilayer OMVPE. Both are compared with material properties of state-of-the-art LPE  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  grown from Te-rich solutions. The  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  layers were grown on bulk CdTe, sapphire ( $\text{Al}_2\text{O}_3$ ) and GaAs substrates. Layers were characterized by optical microscopy, IR transmission, Hall effect, double crystal X-ray diffraction, electron microprobe and secondary ion mass spectroscopy (SIMS). Better crystallinity and smoother morphologies are obtained by conventional OMVPE; interdiffused multilayer OMVPE currently results in better compositional uniformity and reproducibility. The observed differences can be interpreted on the basis of growth kinetics. Both techniques yield  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  epitaxial layers with LPE-like qualities. (Author abstract) 22 refs.

**093685 VAPOR GROWTH OF CdTe AS SUBSTRATE MATERIAL FOR  $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$  EPITAXY.** A specific technique has been established to grow large

single crystal of CdTe from the vapor phase. Investigation of the crystals by X-ray topography, etching techniques and IR microscopy revealed the absence of subgrain boundaries and inclusions, although residual strains were still observed. The substrates are suitable for  $\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$  epitaxy. A novel technique for producing ohmic contacts on p-CdTe is described. (Author abstract) 6 refs.

Geibel, C. (Telefunken Electronic, Heilbronn, West Ger); Maier, H.; Schmitt, R. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 386-390.

**093686 STRUCTURAL DEFECTS IN CdTe CRYSTALS GROWN BY TWO DIFFERENT VAPOUR PHASE TECHNIQUES.** The structural defects present in large single crystals of CdTe grown at the same temperature by two different vapour phase techniques have been investigated using a range of techniques including TEM, SEM, EBIC, EDX and chemical etching. The contrasting defect content of the differently grown crystals can be explained by the considerable difference in the periods taken to grow the crystals by the separate techniques. In the crystals grown by the slower method, the development of both sub-grain boundaries and precipitates reaches a much more advanced stage than in those grown by the faster technique. (Author abstract) 24 refs.

**093687 TEM STUDIES OF EPITAXIAL CdTe AND (Hg, Cd)Te GROWN BY MOVPE ON GaAs AND CdTe SUBSTRATES.** Epitaxial layers of [111]-oriented CdTe have been grown on [111] A CdTe, [111] B GaAs and [100] GaAs by MOVPE. Cross-sectional transmission electron microscope (TEM) studies have revealed the presence of many lamella twins lying parallel to the substrate-layer interface in all of these layers. In contrast, [100] CdTe deposited onto [100] GaAs exhibits a large number of misfit dislocations at the interface. A structural comparison of epitaxial layers of (Hg, Cd)Te deposited onto CdTe/[111] B GaAs hybrid substrates and onto bulk [111] A CdTe substrates is also reported. (Author abstract) 23 refs.

Brown, P.D. (Univ of Durham, Durham, Engl); Hails, J.E.; Russell, G.J.; Woods, J. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 511-515.

**093688 COMPARISON OF THE STRUCTURE OF CdTe AND (Hg, Cd)Te LAYERS GROWN BY MOVPE ON [111]A AND [111]B CdTe SUBSTRATES.** This paper presents a comparison of the structural properties of layers of CdTe and (Hg, Cd)Te grown onto [111]A and [111]B CdTe substrates as determined by the combined techniques of RHEED, SEM and cross-sectional TEM. The interest in the structural properties of homoepitaxial layers of CdTe arises from the fact that this material is often deposited as a buffer layer prior to the deposition of CMT when foreign substrates are employed. It may also be desirable to grow a buffer layer of CdTe before the deposition of CMT on CdTe substrates in order to eliminate the effect of surface contaminants and provide an atomically clean interface. 15 refs.

Hails, J.E. (Univ of Durham, Durham, Engl); Russell, G.J.; Brown, P.D.; Brinkman, A.W.; Woods, J. *J Cryst Growth* v 86 n 1-4 Jan I 1988, II-VI Compd 1987: Proc of the Third Int Conf on II-VI Compd, Monterey, CA, USA, Jul 12-17 1987 p 516-521.

**093689 AUGER ELECTRON SPECTROSCOPY STUDY OF PULSED-LASER EVAPORATED CdTe FILMS ON (100) GaAs<sup>1</sup>.** Pulsed-laser evaporated CdTe films deposited on (100) GaAs substrates have been studied by Auger electron spectroscopy (AES). The depth dependence of chemical composition has been determined from sputtering profiles. The films had a constant chemi-

cal composition within the accuracy of AES. Thermal treatment of GaAs substrate at temperatures as low as 260°C was found to be sufficient for obtaining an O- and C-free post-growth surface of GaAs. The width of the interfacial CdTe-GaAs region was  $\leq 3$  nm, and the interface was Te-rich. A possibility of forming the  $\text{As}_2\text{Te}_3$  layer at the CdTe-GaAs interface has been demonstrated. (Author abstract) 16 refs.

**X-Ray Analysis** See Also CRYSTALS—Epitaxial Growth.

**093690 STRUCTURAL AND STABILITY CHARACTERIZATION OF II-VI SUPERLATTICES STUDIED BY X-RAY DIFFRACTION.** Two II-VI superlattice systems are reviewed:  $\text{Hg}_{1-x}\text{X}_x\text{Te}/\text{CdTe}$  ( $\text{X}=\text{Cd}, \text{Mn}, \text{and Zn}$ ) and  $\text{ZnTe}/\text{CdTe}$  which have been grown by molecular beam epitaxy at 185 and 300°C, respectively, in a Riber 2300 growth system. The first system, of immediate technological importance, is a tunable narrow band gap semiconductor developed for infrared detection. The second is a matched strained-layer superlattice which exhibits unusual elastic properties. Significant interdiffusion is found to occur during the growth of  $\text{HgTe}/\text{CdTe}$  superlattices. This phenomenon seems not to exist to the same extent in the  $\text{ZnTe}/\text{CdTe}$  system. In addition, interdiffusion in  $\text{Hg}_{1-x}\text{X}_x\text{Te}/\text{CdTe}$  superlattices is markedly reduced when  $x < 0$ . The structural and stability aspects are studied by X-ray diffraction as a function of the incident X-ray energy, of the sample temperature during annealing or interdiffusion, and in scanning other directions than that of the growth. (Author abstract) 27 refs.

### Thin Films

**093692 SYNTHESIS OF DIAMOND THIN FILMS HAVING SEMICONDUCTIVE PROPERTIES.** Semiconductive diamond films were fabricated by the thermal filament CVD method. A saturated solution of  $\text{B}_2\text{O}_3$  powder in  $\text{CH}_3\text{OH}$  mixed with acetone was used. The films deposited were identified as diamond by several methods including Raman spectroscopy. By the measurement of electrical properties, the obtained films were found to show p-type conduction. (Author abstract) 6 refs.

**093693 STRUCTURE AND CERTAIN PHYSICAL PROPERTIES OF SEMICONDUCTOR DIAMOND FILMS.** The structural features and electrophysical prop-

erties of films obtained by deposition of a carbon condensate in a glow discharge plasma are studied. It is shown that the film under study is a p-type semiconductor. It is shown that on the whole, diamond semiconductor films are close in electrophysical properties to amorphized silicon and germanium obtained from the gas phase. (Edited author abstract) 17 refs.

**093694 ACCRESCIMENTO DI FILM SEMICONDUCTORI DI DIAMANTE MEDIANTE DEPOSIZIONE PLASMA-ASSISTITA DA FASE VAPORE.** [Growth of Semiconducting Diamond Films by Plasma-Assisted Vapor Deposition.]. Diamond films of 2-20  $\mu\text{m}$  thickness were grown on silicon substrates from a gaseous mixture of methane and hydrogen. By introducing a small amount of diborane gas into the above mixture, bluish boron-doped diamond films that exhibit semiconducting properties have been deposited. The range of experimental conditions that make it possible to obtain the well-known diamond structure has been determined by means of electron diffraction, X-ray diffraction and Raman spectroscopy. (Edited author abstract) 8 Refs. In Italian.

**093695 POSSIBILITY OF THE USE OF AN ELECTROLYTE-INSULATOR-SEMICONDUCTOR (EIS) SYSTEM FOR INVESTIGATING THE PROPERTIES OF  $\text{Ta}_2\text{O}_5$  IN CONTACT WITH AN ELECTROLYTE SOLUTION.** An investigation is conducted of the properties of  $\text{Ta}_2\text{O}_5$  films obtained by the anodic and thermal oxidation of tantalum on silicon surfaces when they are in contact with an electrolyte solution. The investigations carried out showed that the electrical characteristics of the  $\text{Ta}_2\text{O}_5$ -Si structures are greatly dependent on the method used to prepare the  $\text{Ta}_2\text{O}_5$  film. In the case of freshly prepared structures with anodic oxide films, there was no modulation of the differential capacitance of the space-charge region of silicon over the entire range of bias amplitudes investigated. 11 refs.

**093696 OPTICAL SECOND-HARMONIC GENERATION OF MODULATION DOPED  $\text{Ga}_{0.8}\text{Al}_{0.2}\text{As}$  FILM GROWN BY MOLECULAR BEAM EPITAXY.** Absolute values of the second-order nonlinear susceptibility of modulation doped (1 0 0)  $\text{Ga}_{0.8}\text{Al}_{0.2}\text{As}$  are measured through a Q-switched Nd:YAG laser with self-calibrated power emanating in p-polarization. The angular variation of the reflecting second-harmonic wave agrees satisfactorily with the Bloembergen and Pershan theory. The nonlinear susceptibility of  $\text{Ga}_{0.8}\text{Al}_{0.2}\text{As}$  grown by MBE method is 20% larger than that of GaAs. A quasi-photon counting technique exploited in this experiment provides the possibility to detect the second harmonic reflecting coefficients as low as  $10^{-21} \text{ cm}^2/\text{watt}$ . **093699 LUMINESCENT AND ELECTROPHYSICAL PROPERTIES OF POLYCRYSTALLINE PbTe FILMS.** Lead halogenide films are widely used in electrooptics for creating radiation receivers and sources. Because of this development of methods for testing the parameters of films of these materials and the structures based on this is a current issue. The method of local cathode luminescence (CL), which is quite well developed in application with respect to A<sup>111</sup>BV and A<sup>111</sup>BV compounds is an effective method for investigating the properties of semiconductors. This work presents the results of investigations of local luminescent and certain electrophysical properties of polycrystalline PbTe films. (Edited author abstract) 9 refs.

**093700 HIGH-RATE DEPOSITION OF a-Si:H FILM WITH A SEPARATED PLASMA TRIODE METHOD.** The separated plasma triode (SPT) method has been developed to deposit high-quality a-Si:H films at high deposition rates. Plasma properties were measured by a probe method and an optical emission spectroscopy (OES) method. It is possible to improve the electron density in a plasma without increasing the plasma potential near the substrate by the SPT method. High-quality a-Si:H films and high-performance a-Si solar cells were obtained at high deposition rates using the SPT model. (Author abstract) 19 refs.

**093701 PHOTO-INDUCED POTENTIAL BARRIER IN As-Se-Ge FILMS.** Photo-excited effects in As-Se-Ge and As-Se-Ge-Sn amorphous films have been

studied under illumination of different light sources. As-Se-Ge system exhibited rectifying characteristics under illumination of light with  $h\nu > E_g$ , while As-Se-Ge-Sn film did not show such phenomena. The illumination of the IR light along with the light of  $h\nu > E_g$  weakened the rectification behavior. The photovoltage and I-V characteristics results suggest the existence of "photo-induced" potential barrier in the As-Se-Ge system, which is considered to concern the creation and destruction of neutral defect states D'. (Author abstract) 12 refs.

**093702 AMORPHOUS CuInSe<sub>2</sub> FILMS.** This paper describes the deposition of amorphous p-CuInSe<sub>2</sub> films by flash evaporation and for the first time by co-evaporation. The results of temperature dependence of dc conductivity on one each film of flash and co-evaporation and their energy gap (mobility edge) determination by a new technique - photoacoustic absorption spectroscopy (PAS) are also reported. At 300 K the conductivity values of flash and co-evaporated films are  $9 (\Omega\text{cm})^{-1}$  and  $10^{-3} (\Omega\text{cm})^{-1}$  respectively. Conductivity values strongly depend on Cu/In and Se/(Cu+In) ratios which in turn are preparation dependent. An energy gap of  $1.03 \pm 0.02$  eV and  $1.05 \pm 0.02$  eV are resulted from PAS measurements which are close to the band gaps of the polycrystalline material but far less than that reported in literature of the amorphous films. (Author abstract) 6 refs.

## Analysis

**093703 NONDESTRUCTIVE SURFACE ANALYSIS BY NUCLEAR SCATTERING TECHNIQUES.** An elastic-recoil detection (ERD) technique is developed and successfully applied in the simultaneous, nondestructive multielement depth-profile studies of thin films with thicknesses up to 2  $\mu\text{m}$ , used in various material technologies. In this technique, the light elements are knocked out of the target by using an energetic heavy-ion beam obtained from the Tandem Accelerator Facility of the Nuclear Physics Laboratory. A time-of-flight method is used to separate the masses and the energies of the recoiled elements as well as the Rutherford backscattering incident ions. Using 30 MeV <sup>35</sup>Cl as the beam probe, we get an observed surface resolution of better than 100 Angstrom at a 30° detection angle. Typical mass resolutions for energies < 5 MeV are 0.2 amu in the C region and 0.7 amu in the Si region. The factors related to the mass and depth resolutions, probing depth, and approximate detection limit are systematically studied using <sup>19</sup>F, <sup>35</sup>Cl, and <sup>79</sup>Br as incident beams. This newly developed ERD method, along with the already existing Rutherford backscattering (RBS) technique, makes the Nuclear Scattering Facility at the Universite de Montreal unique for surface analysis. (Author abstract) 14 refs.

## Chemical Deposition

**093704 LASER DEPOSITION OF MATTER FROM THE GAS PHASE AND MASS TRANSFER IN THE BEAM FIELD.** The authors report on the deposition (induced by radiation of a CO<sub>2</sub> laser) of boron particles from the gas phase of molecules of alkenes HCIC=CBCl<sub>2</sub>H, and also on mass transfer of particles along the beam onto which the processes of isotopically

selective multiphoton dissociation and secondary chemical reactions are superimposed. The latter results in the quantitative difference: a. in the mass of the material of the film deposited on the inlet and outlet windows of the reactor; b. in the isotope composition of boron in these films. Various possible mechanics which may cause this phenomenon are discussed. (Author abstract) 14 refs.

**093705 STUDY AND CHARACTERIZATION OF PECVD OXIDES.** Plasma enhanced chemical vapor deposited (PECVD) silicon oxide films used as final passivation layers in MOS-LSI technology are prepared by the reaction of silane and nitrous oxide in a parallel plate radial flow plasma reactor. Deposition parameters (temperature, rf power, and the reactant gas ratio) were systematically varied for finding optimum process parameters for better yields. The film composition and properties for samples deposited at different condition are characterized by measuring the IR spectra, deposition rate, etch rate, and annealing behavior and are compared with thermally grown silicon oxide films. (Author abstract) 7 refs.

**093706 PLASMA DEPOSITION OF HYDROGENATED AMORPHOUS SILICON FILMS.** The purpose of this paper is to summarize aspects of glow discharge relevant to the deposition of high-quality hydrogenated amorphous silicon materials and to elucidate the effects on these films and devices of various deposition parameters and other aspects of the growth process, to better understand how the films are formed. Common diagnostic measurement techniques for determining plasma composition and film properties are reviewed. Also discussed are some effects on film quality of the deposition-system design, including the electrode geometry, bias control, and plasma confinement, and the effects of the most significant deposition parameters, such as power density, substrate temperature, feed-gas concentration, pressure, and gas flow rate. Special emphasis is placed on avoiding contamination from impurities and avoiding the structural inhomogeneities that can result from microparticulates in the plasma or from ion bombardment of the growing film. (Edited author abstract) 213 refs.

Luft, Werner (Solar Energy Research Inst, Golden, CO, USA); Tsuo, Simon. *Appl Phys Commun* v 8 n 1 Mar 1988 p 1-74.

**093707 PLASMA-DEPOSITED FILMS: KINETICS OF FORMATION, COMPOSITION, AND MICROSTRUCTURE.** A number of inorganic and organic materials have been synthesized by plasma-enhanced chemical vapor deposition (PECVD) techniques, in which the precursor gases are decomposed in a glow discharge, and the thin films can be grown on substrates at temperatures below 300°C. Plasma-deposited silicon nitride and silicon dioxide are widely used as encapsulating materials for the final passivation of very large scale integrated (VLSI) circuits. In recent years, glow discharge-produced amorphous silicon has attained considerable importance as a new electronic material for fabricat-

ing thin film devices such as solar cells, transistors, sensors, and photoreceptors. Very extensive work on this material is in progress to characterize the electronic and structural properties of amorphous silicon films as well as to understand the growth kinetics. Further developments of plasma CVD techniques to prepare metal thin films or novel organic materials are expected in the near future, based upon better understanding of the deposition chemistry in the glow discharge. The author examines deposition variables, the composition and chemical bonding of the deposited flow, radial beam deposition and the silicon growth process. 39 refs.

Hirose, Masataka (Hiroshima Univ, Higashihiroshima, Jpn). *Plasma Deposited Thin Films* Publ by CRC Press Inc, Boca Raton, FL, USA, 1986 p 21-43.

**093708 PLASMA DEPOSITION OF HYDROGENATED AMORPHOUS SILICON FILMS.** Plasma-assisted chemical vapor deposition has become the most common technique used in the deposition of hydrogenated amorphous silicon films and devices for photovoltaic applications. The purpose of this paper is to summarize aspects of glow discharge relevant to the deposition of high-quality hydrogenated amorphous silicon materials and to elucidate the effects on these films and devices of various deposition parameters and other aspects of the growth process, to better understand how the films are formed. Common diagnostic measurement techniques for determining plasma composition and film properties are reviewed. Also discussed are some effects on film quality of the deposition-system design, including the electrode geometry, bias control, and plasma confinement, and the effects of the most significant deposition parameters, such as power density, substrate temperature, feed-gas concentration, pressure, and gas flow rate. (Edited author abstract) 213 Refs.

Luft, Werner (Solar Energy Research Inst, Golden, CO, USA); Tsuo, Simon. *Appl Phys Commun* v 8 n 1 Mar 1988 p 1-74.

**093709 ArF LASER PHOTOCHEMICAL VAPOR DEPOSITION OF Si FILMS WITH VARIOUS CARRIER GASES.** Amorphous 0.1  $\mu\text{m}$  to 0.3  $\mu\text{m}$  thick Si films of optical homogeneity with a photoconductivity to dark conductivity ratio of  $10^5$  were obtained at substrate temperatures of approx. 200°C. The deposition rate - influenced by light intensity, gas flow, gas pressure and substrate conditions - was approx. 1 nm/min to 5 nm/min. In-situ ion current measurements suggest that each deposition shower initiated by a short 30 ns laser pulse lasts up to 100  $\mu\text{s}$ . One of the most significant observations was the high  $\text{Si}_2\text{H}_6$  excitation selectivity of the photo-CVD process without the carrier gas, e.g. He, Ar or  $\text{N}_2$ , excessively influencing the photoconductivity of the Si films. (Author abstract) 10 Refs.

**093710 CRYSTALLIZATION OF SUPERCOOLED INSULAR FILMS OF BINARY ALLOYS OF THE Pb-Bi(Sn) AND Sn-Bi SYSTEMS.** The temperatures of the attainable supercoolings and the corresponding crystal nucleation frequencies in insular films of alloys of the Pb-Bi, Pb-Sn and Sn-Bi systems were determined experimentally. In alloys of the Pb-Bi and Sn-Bi systems, the nature of the concentration dependence of the temperature of the attainable supercoolings in the range corresponding to solid solutions is in qualitative agreement with theoretical predictions. In the Pb-Sn alloy, a more complex dependence is observed. In Russian. 13 refs.

**093712 BPSG FILMS DEPOSITED BY APCVD.** The recent substitution of borophosphosilicate (BPSG) glasses for phosphosilicate glass (PSG) films has significantly eased the conditions needed to reflow the planarizing glass films and to achieve the topographies required to promote continuous metal and insulator step coverage. This article examines some of the relationships between deposition conditions and film characteristics for BPSG films deposited in a continuous, atmospheric CVD reactor. The authors present observations of BPSG reflow behavior as it relates to film dopant concentration and reflow anneal conditions. 5 refs.

**093713 EFFECT OF INDIUM ON THE ELECTRICAL TRANSPORT PROPERTIES OF  $\text{Pb}_{0.8}\text{Sn}_{0.2}\text{Te}$  THIN FILMS.** Hall coefficient and dc conductivity studies were made in the 77-300K temperature range on  $\text{Pb}_{0.8}\text{Sn}_{0.2}\text{Te}$  films doped with different concentrations of indium. Indium was found to give donors, and the values of the Hall coefficient and the Hall mobility were found to decrease with an increase in the doping concentration of indium. Analysis of mobility data revealed that lattice and defect scatterings are predominant in these films. (Author abstract) 17 refs.

**093718 SURFACE-STATE GENERATED CURRENTS IN THIN SEMICONDUCTOR LAYERS.** The conditions for the formation of a regime of currents which are bounded by the surface states in thin layers of semiconductors are studied. It is shown that these conditions consist of a strong reduction in the near junction barrier by the heating electric field and localization of injected charge in the near-surface region owing to a developed spectrum of centers on the surface of the semiconductor. Working formulas are obtained for determining the surface charge, the near-surface conductivity and also the depth of the centers near the surface and their density in a model with a monoenergetic distribution of these centers over the current voltage characteristic. The conditions for distinguishing a given mechanism from other mechanisms of current flow are determined. (Author abstract) 13 refs.

**093721 TUNNELLING MAGNETO-PLASMONS AND ANDERSON LOCALISATION IN SEMICONDUCTOR SUPERLATTICES.** We present a theory of magneto-plasmons in tunnelling semiconductor superlattices. A new plasmon branch is predicted, which is due to the mini-band energy dispersion in the superlattice direction. This tunnelling plasmon branch is sensitive to disorder. Anderson localization (AL) of the electron states causes its frequency to decrease, scaling according to the AL length until the plasmon disappears due to Landau damping at low frequencies. Experimental implications are discussed. (Author abstract) 24 refs.

**093722 ELECTRONIC PROPERTIES OF PLASMA-DEPOSITED AMORPHOUS SEMICONDUCTOR FILMS.** This chapter treats the basic properties of amorphous films deposited in a glow discharge. A glance at the programs of international conferences on amorphous semiconductors shows that amorphous silicon (a-Si:H) prepared by plasma decomposition of silane ( $\text{SiH}_4$ ) plays a dominant role in this field. In addition, the study of this material is expected to help in reaching a better understanding of the physics of disordered materials in general. By using glow discharge techniques, one can obtain a much lower defect density in the films, as compared to other deposition techniques, due to the incorporation of hydrogen atoms. This beneficial effect of hydrogen incorporation also leads to good semiconducting properties in a-Ge:H films deposited from germane ( $\text{GeH}_4$ ) and in amorphous alloy films such as a- $\text{Si}_{1-x}\text{Ge}_x$ :H, a- $\text{Si}_{1-x}\text{C}_x$ :H, a- $\text{Si}_x\text{N}_{1-x}$ :H, and a- $\text{SiO}_x$ :H, which are obtained from the deposition of gas mixtures of silane with  $\text{GeH}_4$ , hydrocarbons,  $\text{NH}_3$ , and  $\text{N}_2\text{O}$ , respectively. These alloy films are of great practical interest. The present chapter concentrates mainly on those electronic properties of a-Si:H films which are regarded as relevant for the various technical applications of this material. 169 refs.

**093723 ELECTRON TRANSPORT AND PHOTOELECTRIC PROPERTIES IN GLOW DISCHARGE a-Si:H FILMS PREPARED FROM DISILANE.** The electron transport and photoelectric properties in a-Si:H films prepared from disilane by an rf glow-discharge decomposition process have been measured as a function of substrate temperature and have been compared with those prepared from monosilane. The temperature dependence of the electron mobility reveals a significant difference in the tail state distribution below the conduction band between disilane and monosilane films. This

suggests the local atomic structures of a-Si:H films depend critically on source gas species, even if the room-temperature properties are apparently the same. (Edited author abstract) 17 refs.

**093724 STRUCTURE AND ELECTROPHYSICAL PROPERTIES OF LAYERS OF  $\text{Pb}_{1-x}\text{Cd}_x\text{S}$  SOLID SOLUTIONS.** Epitaxial layers of  $\text{Pb}_{1-x}\text{Cd}_x\text{S}$  solid solutions of both n- and p-types have been grown by a 'hot wall' method. It is shown that, when a mechanical mixture of lead sulfide and cadmium sulfide is used as the source, the composition of layers of  $\text{Pb}_{1-x}\text{Cd}_x\text{S}$  solid solutions can be controlled within the range  $1 \leq x \leq 10 \text{ mol.}\%$  CdS by varying the substrate temperature. A decrease in the substrate temperature caused an increase in the CdS concentration in the layers. However, at substrate temperatures less than 673 K the structural perfection of the layers deteriorated. In the case of p-type layers the Hall coefficient did not depend on temperature, while in the case of n-type layers it decreased monotonically with an increase in temperature. With an increase in x the electron and hole mobilities decreased. 8 refs. In Russian.

**093725 STUDY OF  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  EPITAXIAL FILMS DEPOSITED BY MBE TECHNIQUE.** Epitaxial films of  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  (LTT) were deposited on (100) KCl substrates at 300, 325 and 350°C using Molecular Beam Epitaxial (MBE) technique. RHEED, X-ray and Van der Pauw techniques were employed to study surface structure, single crystallinity and electrical properties of these films respectively. The resistivity of these films was found to decrease from  $10^{-2} \Omega\text{-cm}$  at 300K to  $10^{-3} \Omega\text{-cm}$  at 100 K. The mobility was found to increase with lowering of temperature in the range  $10^2 \text{ cm}^2/\text{V sec}$  at 300 K and  $10^3 \text{ cm}^2/\text{V sec}$  at 100 K. (Author abstract) 22 refs.

**093728 CHARACTERIZATION OF EPITAXIALLY GROWN SEMICONDUCTIVE LAYERS BY SCATTERING OF OPTICAL PSEUDO-SURFACE WAVES AND INTERFERENCE FRINGES DUE TO GUIDED WAVES WITHIN THE LAYERS.** When optical pseudo-surface waves are generated by a nearly critical transmission condition, their scattering is very useful for observation of defects, such as dislocations and microcracks near surfaces and also for detection of scratches and dust on the surfaces. Guided waves created by multiple reflections between interfaces make equal-thickness fringes by which fluctuation of their thickness is observed. (Author abstract) 3 refs.

Ogawa, Tomoya (Gakushuin Univ, Tokyo, Jpn). *Jpn J Appl Phys Part 2* v 26 n 10 Oct 1987 p 1638-1641.

**093729 DIFFUSION OF TIN IN A  $\text{PbSe}_{1-x}\text{Te}_x$  SOLID SOLUTION.** A study was made of the diffusion of tin in single crystals of a solid solution of lead selenide and lead telluride by the radioactive tracer method using the  $^{113}\text{Sn}$  isotope. It was found that the diffusion conditions correspond to the conditions of synthesis of  $\text{Pb}_{0.8}\text{Sn}_{0.2}\text{Te}$  epitaxial layers on  $\text{PbSe}_{0.08}\text{Te}_{0.92}$  by the vacuum condensation method. Various diffusion mechanisms were noted in the 350-500°C temperature range, and their activation energies were determined. It is shown that the diffusion of tin in  $\text{PbSe}_{0.08}\text{Te}_{0.92}$  may be represented within the framework of a 'dissociative mechanism' model. In Russian. 6 refs.

Simirskii, Yu.N.; Krylyuk, O.N.; Gas'kov, A.M.; Zlomanov, V.P. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 8 Aug 1987 p 1278-1281.

**093730 CHARACTERIZATION OF REACTIVELY SPUTTERED TIN FILMS.** Tin films were grown on 4 inch silicon substrates by dc magnetron sputtering from a pure Ti target in an  $\text{Ar}/\text{N}_2$  atmosphere. The influence of deposition parameters (e.g., gas composition, substrate bias, and temperature) on film properties were examined by means of x-ray diffraction, and measurement of resistivity, stress, and density. 18 refs.

Cirelli, Nadia (SGS, Agrate, Italy); Hems, John. *Solid State Technol* v 31 n 2 Feb 1988 p 75-78.

**093731 GROWTH AND CHARACTERIZATION OF GERMANIUM AND BORON DOPED SILICON EPITAXIAL FILMS.** The epitaxial growth and characterization of in-situ germanium and boron (Ge/B) doped Si epitaxial films is described. As indicated by secondary ion mass spectroscopy and spreading resistance measurements, the total and electrically activated B concentrations are essentially identical and independent of Ge incorporation. The B and Ge concentrations are uniformly distributed in these Ge/B doped films. A slight enhancement of Hall mobility is obtained, possibly due to the stress relief induced by Ge counterdoping. Electron injection reveals a different transport mechanism of the  $\text{SiO}_2$  grown on these Ge/B doped films. (Edited author abstract) 7 refs.

Ang, Simon S. (Texas Instruments Inc, Dallas, TX, USA); Garvin, James F., Jr. *J Electron Mater* v 17 n 1 Jan 1988 p 39-43.

**093732 GROWTH OF POLYANILINE FILMS: EVIDENCE FOR FRACTAL SURFACE.** During electropolymerization of aniline using cyclic potential scanning the surface area of the polyaniline films grows like a power law of their volume, with the exponent  $\alpha \approx 0.4$ . Implications of this result are discussed. (Author abstract) 5 refs.

Villeret, B. (CEN de Grenoble, Grenoble, Fr); Nechtschein, M. *Solid State Commun* v 64 n 4 Oct 1987 p 435-437.

**093733 LPE GROWTH OF InGaAsP EPITAXIAL LAYERS OF GaAs SUBSTRATES.** The effects of various growth conditions on surface morphology and compositional nonuniformity of LPE (liquid phase epitaxial) layers of  $\text{In}_x\text{Ga}_{1-x}\text{As}_y\text{P}_{1-y}$  ( $y < 0.01$ ) on (100) GaAs substrate are studied. The growth conditions for obtaining a smooth and uniform layer are found from the results of the changes in surface morphology. The interface instability occurring under undercooling conditions in the LPE process is studied by means of an analysis of the Fourier spectra of the surface morphology. Compositional nonuniformity of InGaAsP LPE layers are investigated by means of precision X-ray diffractometry. The compositional variation taking place in the initial growth stage over several seconds is found. The variation in the initial stage is analyzed theoretically from the 'growth lines' on the In-Ga phase diagram for a diffusion-limited growth model. (Edited author abstract) 24 refs.

**093734 THERMODYNAMIC ANALYSIS OF THE CONCENTRATION PROFILES OF EPITAXIAL LAYERS OF NONIDEAL SOLID SOLUTIONS.** On the basis of a thermodynamic analysis using the quasi-regular approach, a mathematical model of the process of equilibrium crystallization of non-ideal three-component solid solutions of compounds of  $\text{A}^{\text{III}}\text{B}^{\text{V}}$  type from a limited volume of melt solution is constructed. This model makes it possible to calculate the distribution of the components along the thickness of the epitaxial layer at low rates of cooling of the melt solution. Computer calculations of the concentration profiles of  $\text{Ga}_{1-x}\text{Al}_x\text{As}$  epitaxial layers showed good agreement with experimental data for epitaxial-layer thicknesses up to 20  $\mu\text{m}$ . At high cooling rates mass transfer processes in the bulk of the melt solution must be taken into account. In Russian. 12 refs.

Kazakov, A.I. (Kishmar, I.N.); Mokritskii, V.A.; Yakubovskii, M.V. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 10 Oct 1987 p 1602-1606.

**093735 CRYSTALLIZATION OF  $\text{Ga}_x\text{In}_{1-x}\text{As}_y\text{Sb}_{1-y}$  SOLID SOLUTIONS ON GaSb AND InAs SUBSTRATES.** The melt compositions and supercoolings required for the crystallization of  $\text{Ga}_x\text{In}_{1-x}\text{As}_y\text{Sb}_{1-y}$  solid solutions which are isoperiodic with GaSb and InAs substrates were determined. An estimate is made of the composition range of the solid solution ( $\delta \leq \gamma \leq 0.3$ ) which can be grown on GaSb substrates from a supercooled (supersaturated) liquid phase. It is shown that, above 820 K, films of solid solutions corresponding in composition to the central part of the isoperiodic lines cannot be obtained. In Russian. 9 refs.

Bochkarev, A.E.; Gal'gazov, V.N.; Dolginov, L.M.; Selin, A.A. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 10 Oct 1987 p 1610-1614.

**093736 DEPOSITION OF EPITAXIAL SEMICONDUCTOR LAYERS FROM THE LIQUID AND GASEOUS PHASES ONTO A MOVING SUBSTRATE.** Growth from a melt solution on a moving substrate possesses an instability related to trapping of liquid phase from the container. However, in a static regime it is possible to obtain large-block textured silicon and gallium arsenide films on graphite substrates. The conditions for temperature-gradient zone melting through the gaseous-phase or vacuum zone are determined for the growing

of single-crystal or polycrystalline Si and GaAs films on moving substrates. 4 refs. In Russian.

**093739 CONTRIBUTION TO THE UNDERSTANDING OF FILM-SUBSTRATE INTERFACIAL STRUCTURE EVOLUTION SUBSEQUENT TO FILM GROWTH.** The author analyses the present state of art of the understanding of film-substrate interfacial geometry evolution subsequent to film growth. The observed trends are discussed within the frame of a simple microscopic theory based upon the soft phonon theory of interfacial geometrical transitions in film-substrate systems. For a softer film on a stiffer substrate, the main issues are: (i) the film growth can produce an interfacial reconstruction, (ii) an increase of the interfacial bonding acts as a factor stabilizing the interfacial crystallographic structure. (iii) the stability of the interfacial geometry increases as the elastic properties of the film and of the substrate become closer. (Author abstract) 12 refs.

**093740 GROWTH OF GAINAS/INP BY THE VAPOR PHASE EPITAXY HYDRIDE METHOD.** The hydride method was used to study the  $\text{Ga}_x\text{In}_{1-x}\text{As}$  deposition process on <100> InP-wafers. The effects of the vapor pressures of arsenic and metal chlorides on the composition  $x$  have been investigated in order to optimize the lattice matching to InP. These studies were carried out with a reactor designed to obtain sharp interfaces and to make possible an in situ surface analysis by ellipsometry. Thin film deposition on the substrate without heteronucleation at the entry of the deposit zone was achieved by using an additional HCl line. The  $\text{Ga}_x\text{In}_{1-x}\text{As}$  layer matching to the InP substrate required a value of  $[\text{In Cl}]/[\text{Ga Cl}] \approx 20$ . (Edited author abstract). 25 Refs.

**093741 C-V & IR ABSORPTION STUDY OF THIN OXIDE ( $\approx 500 \text{ \AA}$ ) FILMS THERMALLY GROWN ON SILICON.** Results of C-V and IR studies on Si-SiO<sub>2</sub> systems of thin oxides thermally grown on Czochralski (CZ) and float zone (FZ) wafers are reported. The oxides were grown at 900°C in dry oxygen as well as in TCE ambient to get  $\approx 500$  angstrom thick SiO<sub>2</sub>. The oxide thickness was accurately measured by ellipsometer and capacitance methods. IR absorption spectra revealed the peaks for Si-O and O-Si-O stretching bonds at  $830 \text{ cm}^{-1}$  and  $1090 \text{ cm}^{-1}$  respectively. An extra peak at  $1250 \text{ cm}^{-1}$  was also observed, indicating the presence of SiCH<sub>3</sub> which was used for fixing the sample. The variation of interface state density  $N_{it}$  with energy showed an oscillatory behavior at the mid-gap in dry oxide samples along with an increase at the band edges, whereas in TCE oxide samples a smoother variation in  $N_{it}$  was noted. (Author abstract). 17 Refs.

**093742 EPITAXIAL GROWTH OF PbTe ON (100) GaAs SUBSTRATES.** The growth of PbTe films on GaAs by molecular beam epitaxy was studied by reflection high energy electron diffraction. The strains in the films were investigated by X-ray diffraction. Despite a lattice mismatch of 14.2 percent, oriented films can be grown up to a thickness of 4000 angstrom. For thicker films the thermal strain causes cracks if the samples are cooled from growth to liquid-nitrogen temperature. (Edited author abstract). 11 Refs.

## Impurities

**093743 PRELIMINARY IMPURITY ANALYSIS OF  $\text{CuInSe}_2$  THIN FILMS USING THE ELASTIC RECOIL DETECTION METHOD.** Knowledge of impurities in thin films is important for fabrication and characterization of photovoltaic devices. The light-impurity distribution in electrodeposited  $\text{CuInSe}_2$  thin films has been investigated by an elastic recoil detection method using a 30 MeV <sup>35</sup>Cl beam and identifying the recoil masses using a time-of-flight technique. It was found that both oxygen and hydrogen were present and distributed uniformly throughout the thickness studied. Upper limits for carbon and nitrogen were also established. The energy spectra for oxygen and hydrogen were deconvolved to obtain the relative concentrations as a function of depth. Using the same technique, the compositional uniformity of Cu, In and Se was also determined, yielding results qualitatively consistent with those obtained by secondary ion mass spectroscopy. (Edited author abstract). 6 Refs.

## Mathematical Models

**093744 ANALYTICAL MODEL OF FLOW DICHROISM IN LANGMUIR-BLODGETT FILMS.** A model of flow orientation has been developed for analyzing the dichroism in Langmuir-Blodgett (LB) films by introducing a two-dimensional fluid and a sink, which represent the monolayer and a substrate, respectively. The angular distribution function derived using the velocity gradient given by the ideal-fluid approximation satisfactorily explains the data of dichroism in the mixed LB films of a dye and a fatty acid prepared with different velocities.

The results are consistent also with those of the line-shape analysis of ESR spectrum reported previously. (Author abstract) 12 refs.

### Measurements

**093745 ANGULAR DISTORTIONS AND THE EXPONENTIAL ABSORPTION EDGE OF SILICON-RICH  $a\text{-Si}_x\text{N}_y\text{H}_z$  ALLOYS.** Raman Scattering, Photothermal Deflection Spectroscopy (P.D.S.) and optical transmission measurements have been performed on the same samples from two sets of Silicon-rich ( $y/x \leq 0.8$ )  $a\text{-Si}_x\text{N}_y\text{H}_z$  films prepared under widely different conditions in two glow-discharge reactors. The opening of the optical gap  $E_G$  with rising Nitrogen concentrations is linear with the increase of the reciprocal slope  $E_0$  of the Urbach edge. Because of the strong correlation observed between this last parameter and the width of the 'optic' inelastic scattering peak, the broadening of the valence band tail with Nitrogen incorporation was attributed to an increasing r.m.s. standard deviation of the Silicon-Silicon bond angle distribution. (Author abstract) 36 refs.

**093746 ERROR REDUCTION IN THE ELLIPSO-METRIC MEASUREMENT ON THIN FILMS.** A theoretical study on the error reduction scheme for ellipsometry in a paper by Ho et al. to measure ultra thin film ( $<200\text{\AA}$ ) is presented. The study is on a more general double-layer model which can be simplified to the single-layer model. It is shown that the errors can be reduced by at least 5 times for the double-layer structure and 2 times for the single-layer structure. A  $\phi_0$ - $T_1$  plot is devised to reduce the random errors which is useful to determine the index profile of a double-layer thin film. (Edited author abstract). 22 refs.

### Microscopic Examination

**093747 TRANSMISSION ELECTRON MICROSCOPIC STUDY OF THE ELECTROCHROMIC MATERIAL BIS(PHTHALOCYANINATO) YTTERBIUM.** Transmission electron microscopy has been used to characterize thin solid films of bis(phthalocyaninato) ytterbium which were prepared by subliming powder, in vacuo, onto unheated carbon-coated glass substrates. The films are found to consist of three main growth forms: (i) highly crystalline monocrystals in the form of rectangular parallelepipeds, (ii) less perfect, thinner rectangular-shaped monocrystals than type (i), and (iii) very small, finely distributed molecular clusters and strings. The crystallinity of types (i) and (ii) is degraded by electron irradiation, but the use of low-dose methods has enabled the following crystallographic parameters to be determined from the microcrystals by means of both lattice images and electron diffraction: crystal system: face-centered tetragonal, unit cell parameters:  $a=b=28.02\pm0.48$  Å,  $c=6.92\pm0.10$  Å. Variations of cell parameters outside the error limits are shown to be statistically significant and are believed to indicate the presence of a structural variant. Several forms of crystal defects have been imaged and identified. (Author abstract) 22 refs.

**093748 ENERGY GAP AND OPTICAL DIELECTRIC CONSTANT OF  $\text{Pb}_{1-x}\text{Cd}_x\text{Se}$  FILMS.** The transmission spectra of laser-deposited  $\text{Pb}_{1-x}\text{Cd}_x\text{Se}$  films ( $x=0, 0.02, 0.05, 0.08$  and  $0.12$ ) have been measured over the energy range  $0.1\text{--}0.65$  eV at two different temperatures 90 and 300 K. From these spectra the dispersion of the refractive index and the absorption coefficient-energy dependence have been obtained. Thus the dependences of the gap and the optical dielectric constant on the Cd content  $x$  have been investigated. The experimental results have been discussed in the framework of the recently developed theoretical model by Volkov and Pankratov et al. (Author abstract) 17 refs.

**093752 ELECTRICAL & OPTICAL PROPERTIES OF  $\text{CdSb}_2\text{S}_4$  FILMS & THEIR USE IN ECPV CELLS.**  $\text{CdSb}_2\text{S}_4$  films have been deposited onto conducting and nonconducting glass substrates at an optimised substrate temperature following spray pyrolysis technique. The composition of films is nearly stoichiometric and the films exhibit characteristics of a direct band gap semiconductor with n-type conductivity. From values of dynamic V-I characteristics, it is inferred that electrochemical photo-voltaic cells made up of n- $\text{CdSb}_2\text{S}_4$ , 0.5M KCl, 0.5M  $\text{Fe}^{2+}$ , 0.5M  $\text{Fe}^{3+}$  IC are good generators of electricity. The efficiency and fill factor are found to be 0.0084 percent and 33.46 percent respectively. (Author abstract). 9 Refs.

**093753 INVESTIGATION ON PHYSICAL PROPERTIES AND STRUCTURE OF AMORPHOUS HYDROGENATED CARBON FILMS.** Hydrogenated amorphous carbon films were prepared by glow-discharge decomposition of pure  $\text{CH}_4$  at different gas pressure. Results of a study of optical and electrical properties and of the bonding and structure of the films are presented. The values of optical constants are close to those of dense hydrocarbons and nearly independent of gas pressure. Measurements of the temperature dependence of electrical conductivity indicate a conduction by extended states. The results of infrared spectroscopy indicate the existence of a hydrogen-rich phase with saturated groups. (Edited author abstract) 18 refs.

### Plasmas

**093754 FIELD THEORETICAL TREATMENT OF PLASMA MODES IN COUPLED TWO-DIMENSIONAL SYSTEMS.** We investigate an assembly of two two-dimensional electron systems separated spatially but coupled by Coulomb interaction. The acoustic and the optical plasma modes are studied using a field theoretical method. It is found that a certain approximation in treating one class of diagrams gives an effective exchange potential equal to that calculated using the method of Kohn and Sham. For small wave-vector, expressions equivalent to Boltzmann equations are obtained. Numerical results are obtained for the dependence of the frequency on wave vector and densities of the electron systems. (Edited author abstract) 10 refs.

**093755 RESISTIVITY AND PHOTOCONDUCTIVITY OF PLASMA-SPRAYED POLYCRYSTALLINE SILICON.** Polycrystalline silicon layers of area  $8\text{ cm}^2$  and thickness  $t$  ranging from  $100\text{ }\mu\text{m}$  to  $2\text{ mm}$  were prepared on alumina substrates by plasma spraying silicon powder. For  $t > 500\text{ }\mu\text{m}$ , these layers could be detached from the substrate. The conductivity could be made n or p type by in situ doping. The microstructure, impurity content and resistivity as a function of both phosphorus and boron doping concentrations were studied. The effect of heat treatment on the resistivity, Hall mobility and the photoconductivity is reported. The data are explained qualitatively on the basis of existing models of the transport behavior of polycrystalline silicon. (Author abstract) 27 refs.

### Quality Control

**093756 CELL FOR SEMICONDUCTOR ANODIC OXIDATION, ETCHING, AND PARAMETER MEASUREMENT.** One can recover the dopant profile and major-carrier mobility from measurements of the Hall constant and resistivity made on layerwise oxidation and etching for semiconductor films. This is necessary in devising means of making electronic components. Various types of cell, including ones described recently, are used in research and in routine measurement for these purposes. The authors describe a cell for use with GaAs films grown on seminsulating GaAs. This structure imposes require-

ments much more stringent than those for ordinary silicon and gallium arsenide ones. The cell design involves three major aspects: protecting the ohmic contacts and leads from the corrosive medium, electrolyte mixing, and illumination.

**Space Charge**

**093758 TRANSIENT PHOTOCONDUCTIVITY PROBING OF NEGATIVE BULK SPACE CHARGE EVOLUTION IN HALOGENATED AMORPHOUS SELENIUM FILMS.** A delayed transient photoconductivity technique was applied to probe the time evolution of a negative bulk space charge build-up in chlorine doped amorphous selenium films during the application of an electric field. It is shown that the observed negative bulk space charge density depends linearly on the delay time and can be attributed to thermal generation of holes from mid-gap localized states and their consequent sweep out leaving behind ionic centers. Other possible causes are also discussed. The photoinjected excess hole  $\tau_h$ , obtained by extrapolating to zero delay time, was found to be increased by Cl addition to a-Se whereas the hole drift mobility  $\mu_h$  was reduced by almost the same factor. (Author abstract) 7 refs.

**Surfaces**

**093759 SUBSTITUENT AND METAL-ION COMPLEXATION EFFECTS UPON THE GAS-SURFACE INTERACTIONS OF THIN ORGANIC FILMS.** The dark d.c. surface currents are reported for thin films of organic semiconducting compounds when exposed to dinitrogen tetroxide, hydrogen chloride and chlorine. The magnitudes of the dark currents are a function of the  $\pi$ -electron bonding of the organic framework, and can also be varied (i) by altering the peripheral substituents or

(ii) by metal-complex formation or (iii) by changing the physical characteristics of the films. The possibilities for gas-discriminatory analytical devices are discussed. (Author abstract). 17 Refs.

**093761 PREPARATION OF BISMUTH IODIDE FILMS BY IODINATION OF CHEMICALLY DEPOSITED BISMUTH SULPHIDE FILMS.** c-Axis Oriented bismuth iodide thin films were prepared by iodination of chemically deposited bismuth sulfide thin films. The mechanism of iodination is discussed in the light of the results of x-ray diffraction and electrical resistivity studies with different times of iodination. The replacement of sulfur by iodine in the Bi<sub>2</sub>S<sub>3</sub> lattice is feasible in view of the favorable free energy change. The shift in the optical absorption edge of the iodized films confirms the substitution phenomenon. X-ray fluorescence studies of iodized films washed with carbon disulfide gave evidence of the isolation of sulfur on the surface of the converted BiI<sub>3</sub> film. (Author abstract) 12 refs.

**093762 LOW TEMPERATURE CHEMICAL PREPARATION OF SEMICONDUCTING TRANSITION METAL CHALCOGENIDE FILMS FOR ENERGY CONVERSION AND STORAGE, LUBRICATION AND SURFACE PROTECTION.** A simple technique is presented for the production of films of transition metal disulfides such as MoS<sub>2</sub>, WS<sub>2</sub>, FeS<sub>2</sub>, or RuS<sub>2</sub> by the reaction of transition metal carbonyls with a sulfur source in an organic solvent benzene, toluene, xylene, mesitylene at temperatures ranging between 80 to 165°C. The quality of the materials and films has been investigated, and some applications are discussed. They include use of the chemically prepared sulfides as photoactive materials (e.g., MoS<sub>2</sub>, WS<sub>2</sub>, FeS<sub>2</sub>), as lubricating films (MoS<sub>2</sub>), as electrodes for Li-batteries (MoS<sub>2</sub>, FeS<sub>2</sub>) and for corrosion protection (RuS<sub>2</sub>). (Edited author abstract). 17 Refs.

**093763 PREPARATION OF Zn<sub>x</sub>Cd<sub>1-x</sub>O THIN FILMS.** Investigation has been made on Zn<sub>x</sub>Cd<sub>1-x</sub>O thin films prepared by a sputtering technique. From X-ray diffraction, it was found that the magnitude of the

preferred (002) peak of ZnO decreased as the cadmium concentration was increased. For the rf sputtered Cd-rich films, a preferred (200) plane was observed. It was further found that the crystalline quality of the films was better for the pure materials. The absorption edge obtained from transmission measurements showed a minimum at  $x=0.6$  and an abrupt increase as the  $x$  value was increased from 0.6 to 1. Room temperature electrical measurements showed a strong positional effect for the Zn-rich samples. Good resistivity uniformity was obtained for the Cd-rich films even using the same deposition conditions. (Author abstract) 5 refs.

**093764 ELECTROCHEMICAL SYNTHESIS OF PHOTOACTIVE In<sub>2</sub>Se<sub>3</sub> THIN FILMS.** In<sub>2</sub>Se<sub>3</sub> thin films were grown by alternate electrodeposition of selenium and indium from separate baths onto titanium substrates with subsequent thermal annealing. The influence of annealing temperature on the properties of the obtained films was examined. The results of X-ray diffraction patterns led to the conclusion that films were  $\beta$ -phase when the temperature ranged between 300 and 500°C. At 600°C the thin film loses Se and the ratio Se/In decreases. Only photoanodic response, n-type thin films, was observed when the samples were tested in a photoelectrochemical cell with a sulfite/sulfate redox couple. Values of the photocurrent on the spectra response were increased when the annealing temperature was also increased, showing the best photocurrent values at 500°C, and the films that were annealed at 600°C showed no photoactivity. Additional study results are discussed. (Edited author abstract) 21 refs.

**093766 GALLIUM ARSENIDE: THE 'OTHER' SEMICONDUCTOR FOR MICROCHIPS.** GaAs is one of a class called 'compound semiconductor crystals.' This means that it is formed out of more than just one element from the periodic table; it conducts electricity in a limited, controllable way like silicon; and the different atoms in it form a crystalline structure with a carefully ordered pattern: arsenic atoms alternate with gallium atoms in a precise 1-to-1 sequence. This article describes some of the challenges of bringing this electronic material into commercial production for integrated circuits.

Rogers, David W. (Cominco Ltd, Trail, BC, Can). *ASTM Stand News* v 15 n 10 Oct 1987 p 28-31.

**093767 CHARGE TRANSFER AND STABILIZATION AT ILLUMINATED n-GaAs/AQUEOUS ELECTROLYTE JUNCTIONS.** A simple model for the charge transfer process at various n-GaAs/aqueous electrolyte junctions is proposed. The assumptions made in the model are justified thanks to Electrochemical Photocapacitance Spectroscopy experiments; this technique is of great help in such a matter. As a result, the model accounts very well for the numerous aqueous electrolytes we used. It is found that (i) the more reducing the redox couple the greater the kinetics, i.e. S increases (ii) the more concentrated the redox species the more stabilized the electrode and (iii) the smaller the water concentration the greater S. All the parameters of the model are discussed and physically interpreted. The main results are: (i) the direct transfer for the redox reaction and (ii) the greater S the more pinned at the surface the band edges of the semiconductor. (Edited author abstract) 27 refs.

**093769 GENERATION KINETICS OF EL2 CENTERS IN GaAs.** The generation kinetics of EL2 centers is investigated by means of the optical absorption at low temperature with GaAs in which grown-in EL2 centers have previously been eliminated by annealing at 1200°C. An analysis of the experimental results with chemical rate equations shows that an EL2 center consists of at least three defects of elementary type. The activation energy for the generation of EL2 centers is determined to be about 2.5 eV. The results favor the picture that the kernel of an EL2 center consists of one  $\text{As}_{\text{Ga}}$  antisite and two Ga vacancies. (Author abstract) 10 refs.

**093770 PHOTOCHEMICAL PATTERN ON p-TYPE GaAs.** A photochemical pattern on p-type GaAs has been realized with an electrodeless system. The illuminated zone appears to be above the surface whereas it is etched on n-type sample. The electrolyte is an acidic solution containing  $\text{Fe}^{3+}$  as an oxidizing agent. This solution reacts with the material and particularly with As atom under light leading to  $\text{As}_4\text{O}_6$  growth. (Author abstract) 9 refs.

**093771 BAND-OFFSETS AND EFFECTIVE-MASS PARAMETERS IN QUANTUM WELLS.** The 85% rule for the conduction band-offset of GaAs quantum wells with AlGaAs barriers established by R. Dingle et al. turns out to be an artifact of using inappropriate hole mass parameters. It is shown that band parameters (for hole masses and conduction band nonparabolicity) obtained from adhering to quantum well optical data are consistent with known values for the bulk material. **093773 EFFECT OF HYDROSTATIC PRESSURE ON THE 0.15 eV Cu ACCEPTOR LEVEL IN GaAs.** The evolution of the characteristic photoluminescence (PL) of the 0.15 eV Cu acceptor level in GaAs has been studied as a function of hydrostatic pressure. In the pressure range up to 35 kbar, i.e. in the direct gap region, the Cu-related PL band closely tracks the near-band-edge emission. The pressure derivative of the Cu acceptor level has been determined and is found to be  $0.3 \pm 0.2$  meV/kbar. This number is only a small fraction of the

total pressure derivative of the energy gap which amounts to 10.7 meV/bar, a result similar to our previous findings for the Mn acceptor level in GaAs, for which the pressure derivative was found to be  $1.2 \pm 0.2$  meV/bar. It should be noted that the remaining difference in pressure derivative is significant and beyond the uncertainty of the experimental data. (Edited author abstract). 17 Refs.

**093774 BAND-GAP NARROWING DUE TO MANY-BODY EFFECTS IN n-TYPE DEGENERATE GaAs CRYSTALS.** The band-gap narrowing due to many-body effects in n-type degenerate GaAs crystals is analytically expressed in terms of the total donor concentration, principally on the basis of the integral expressions of conduction-and-valence band edge shifts, established and numerically computed by R.A. Abram et al. in the plasmon pole approximation and a self-energy approach. Here, the additional screened Coulomb hole effect is also considered. Then, the numerical results are compared with the corresponding results deduced from other works. Finally, it is suggested that, at both, very low and high concentrations, the result of band-gap narrowing is reduced to that given by the traditional Hartree-Fock exchange effect, and thus proportional to the cube root of the total donor concentration. (Edited author abstract). 8 Refs.

**093775 SPECTROMETRIE DE PHOTOELECTRONS X ET UV POUR LE SUIVI IN-SITU DE L'EXPOSITION DE GaAs (100) ET (110) A DES PLASMAS MULTIPOLAIRES.** [X-Ray and UV Photoelectron Spectrometry for In-Situ Followup of Exposure of GaAs (100) and (110) to Multipolar Plasmas]. The authors study the interaction of III-V compound surfaces with  $\text{H}_2$  and  $\text{N}_2$  multipolar plasmas. N- and p-doped GaAs (100) wafers underwent a series of short hydrogen deoxidation plasmas. At each of them, XPS analyses provided information about the chemical structure and the position of the Fermi level on the (100) surface. During the early deoxidation phase, the Fermi level moves from a pinning position due to residual oxides to that of a clean GaAs (100) surface covered by at least one monolayer of oxygen. For longer plasma exposures, elemental arsenic seems to yield a new pinning position. UPS analyses were also performed on GaAs (110) surfaces, freshly cleaved in UHV and exposed to  $\text{H}_2$  and  $\text{N}_2$  multipolar plasmas. Attention was paid to both surface contributions in third-core levels and surface structures in valence bands. (Author abstract) 4 refs. In French.

## Adsorption

**093776 TIME-DEPENDENT CHEMISORPTION ON A SEMICONDUCTOR SURFACE.** The microscopic aspects of interfacial growth are only crudely accessible to experiment. We have therefore developed a technique for computer-experimental studies of atoms and molecules deposited on solid surfaces, in which forces are determined from the electronic structure rather than atomic potentials. Here we report simulations of Cl, O, Se, N, As, Si, Ge, Al, Ga, Zn, Hg, Cu, and Au on the (110) surface of GaAs. The results exhibit non-trivial variety in both the dynamics and final bonding sites. (Author abstract) 25 refs.

## Analysis

**093777 THEORETICAL INVESTIGATION OF ENERGY SHIFTS AT THE GaAs/Au INTERFACE.** We have used an image screening model to calculate the shift of the  $Ga(3d^{-1})$  core-level distribution when a GaAs surface is covered with metal. Using the GaAs bulk dielectric constant we find a shift of 0.1 (0.18) eV with a mean free path of 25 (8) Å. These shifts are comparable to the measured ones, indicating that final-state (image) screening represents an important part of core-level shifts in the vicinity of the interface. (Author abstract).

**093778 SEQUENTIAL ETCH ANALYSIS OF ELECTRON INJECTION IN P<sup>+</sup>-GAAS.** The influence of heavy impurity doping of electron injection currents in p<sup>+</sup>-n diodes is investigated experimentally. By extracting the  $n = 1$  diffusion current after successive etches of the p<sup>+</sup>-layer, the electron injection current is characterized. The technique is applied to a metal organic chemical vapor deposition (MOCVD) grown GaAs solar cell Zn-doped  $1.2 \times 10^{10} \text{ cm}^{-3}$  on the p-side. The results, which demonstrate that so-called bandgap narrowing effects enhance the injected electron current, have important implications for the design of GaAs solar cells and bipolar transistors. 11 refs.

**093779 GALLIUM ARSENIDE INTEGRATED CIRCUITS FOR TELECOMMUNICATIONS SYSTEMS.** This paper reviews the status of the GaAs technology and how it may enhance the performance and value of new systems. The higher speed performance being achieved with the first generation of GaAs ICs, now available from several commercial sources, is demanding new features of design, packaging and assessment both for the integrated circuits and for their interconnection of PCBs or hybrids. It also reports on the widening range of laboratory device structures, mostly involving complex epitaxial heterostructures, which will offer another significant improvement in systems performance. Within telecommunications, two important applications for high speed ICs are for long and short haul optical fiber systems and for low cost millimetre-wave radio systems. Variations of the basic GaAs IC device structures can be used for both these applications with much commonality in current and future technologies. For the longer term, many laboratories are developing monolithic optoelectronic ICs (OEICs) to achieve high performance at

reduced cost for increased market penetration. (Edited author abstract) 19 refs.

**093780 TECHNOLOGY CHOICE FOR HIGH-SPEED APPLICATIONS - GaAs OR SILICON.** This paper compares gallium arsenide and silicon technologies for high-speed digital applications. The bases of comparison are physics, engineering and economics. Gallium arsenide is shown to be limited by engineering and economic considerations; true like-for-like comparisons on speed are almost impossible to obtain. Where complexity is low and performance at a premium, gallium arsenide is probably the best choice, but for even modest complexity silicon bipolar will remain dominant. (Author abstract) 4 refs.

**093781 RELATIONSHIP BETWEEN SEGREGATED ARSENIC IN GaAs AND PHOTOLUMINESCENCE AND KINETICS OF ARSENIC SEGREGATION AT ROOM TEMPERATURE.** Arsenic segregation in GaAs passivation/insulation is a major problem in GaAs-based device applications. The extent of arsenic segregation is related to the intensity of photoluminescence observed when a treated GaAs surface is exposed to a laser beam. The relationship is then used to determine the kinetics of the arsenic segregation, which involves a solid-solid reaction for oxygen extraction by gallium from  $As_2O_3$ . The results are applied to literature data. The kinetics determined indicate that the solid-solid reaction could be elementary, at least with respect to the gallium atom concentration. (Author abstract) 16 refs.

**093784 INFLUENCE OF ADSORBED IONS ON CHARGE-CARRIER RECOMBINATION AT THE n-GaAs PHOTO-ANODE SURFACE.** Photocurrent-voltage and capacitance-voltage measurements were performed at the n-GaAs/aqueous electrolyte interface before and after the pre-treatment of the surface in solutions containing  $Pb^{2+}$  or  $Ru^{3+}$ . The results confirm the model, proposed before, in which two types of surface states were assumed to participate in electron-hole recombination, i.e. non-photo-induced states as well as states associated with photodecomposition intermediates, and demonstrate that, whereas the pre-treatment enhances the rate of recombination in the former type of states, it does not significantly affect the rate of recombination in the latter, nor that of interfacial charge transfer. (Author abstract) 11 refs.

**093787 CYCLOTRON MASSES IN n-GaAs/Ga<sub>1-x</sub>Al<sub>x</sub>As HETEROJUNCTIONS.** Electron cyclotron resonance is studied in single layer GaAs/Ga<sub>1-x</sub>Al<sub>x</sub>As heterostructures. The cyclotron mass is measured over a wide range of the two-dimensional electron density  $N_2$  and the magnetic field strength B to enable detailed comparison with self-consistent theoretical results that take into account the effects of band nonparabolicity. The calculations are performed using an effective  $2 \times 2$  subband Hamiltonian, which is derived from a five-level k-p-model by fourth order perturbation theory and includes remote band contributions. Close agreement between experimental and theoretical cyclotron masses is achieved and the importance of band nonparabolicity in these systems is demonstrated. (Author abstract) 12 refs.

**093790 DONOR NATURE OF THE MAIN ELECTRON TRAPS IN ELECTRON-IRRADIATED N-TYPE GaAs.** Of all the electron (E) and hole (H) traps measured by DLTS in 1 MeV electron-irradiated GaAs, two of them, E1 and E2, have much higher production rates (approximately  $2 \text{ cm}^{-1}$ ) than any of the others. By carefully analyzing nine samples which exhibit the type-conversion phenomenon, we show that the net production rate of below-mid-gap acceptors over above-mid-gap donors in n-type samples is  $\tau_{\text{net}} \equiv \tau_A - \tau_D = 0.4 \pm 0.1 \text{ cm}^{-1}$ . This number is consistent with recent temperature-dependent Hall-effect data only if E1 is a donor. We then show that other evidence also strongly favors E2 as a donor, while E3 remains uncertain. The donor nature of E1 and E2 is much more consistent with their identification as As-vacancy related than are other proposed models. (Author abstract) 8 refs.

**093792 PREPARATION OF EXTRA-THIN CHANNEL WITH HIGH CARRIER CONCENTRATION IN GaAs BY SI ION IMPLANTATION THROUGH SiN FILM.** Shallow junctions with high carrier concentration are important for high speed MESFET. By using Si ion implantation through SiN film, thin junctions ( $< 1000 \text{ Å}$ ) with carrier concentrations of  $> 10^{18} \text{ cm}^{-2}$  have been prepared. High doses of Si,  $> 10^{13} \text{ cm}^{-2}$ , and mode-rate energy 80 keV, were found to be suitable. The thickness of the SiN approximately equals the displacement of the carrier concentration peak towards the surface of the wafer. (Edited author abstract) In Chinese. 2 refs.

**093795 EFFECT OF DEEP LEVELS INDUCED BY ELECTRON IRRADIATION UPON THE CHARGE TRANSPORT MECHANISM AND THE PRESSURE-DEPENDENT ELECTRICAL PROPERTIES OF FORWARD-BIASED  $p^+-n-n^+$  GaAs DIODES.** Results are presented on the effect of electron bombardment upon the charge transport mechanism and the pressure-dependent electrical properties of  $p^+-n-n^+$  GaAs diodes. It is shown that at low bias voltage the electron irradiation does not change the charge-carrier transport mechanism. A change of IVC of GaAs diodes induced by increase of the irradiation dose is due to a rise of resistance of the diode base, resulting from a compensation of the base after the bombardment and to the appearance of double injection of the charge carriers into the diode base. It is found that a sublinear section of the IVC, which appears at high irradiation dose, is a result of the formation of a near-anode stationary high-field domain. Analytical expressions are obtained which describe the experimental IVC for the irradiated diodes. The sensitivity of the irradiated diodes to the hydrostatic pressure is described by means of analytical formulas and numerical calculations, taking into account the pressure dependence of the width of the gap, energies of the gap levels induced by irradiation, and the lifetime of the charge carriers injected into the base region. (Edited author abstract) 20 refs.

**093796 ON SPACE-CHARGED-LIMITED CONDUCTION IN SEMI-INSULATING GaAs.** We have measured the temperature dependence of Cr doped semi-insulating (SI) GaAs in planar and point contact configurations at various fields ranging between  $10$  and  $10^6 \text{ V/m}$ . In a planar configuration the transport is ohmic up to approximately  $10^4 \text{ V/m}$  with an activation energy of approximately  $0.75 \text{ eV}$ . At higher fields we have observed a space-charge-limited (SCL) transport with an activation energy of about  $0.47 \text{ eV}$ . In a point contact configuration a quasi-ohmic and a transitional region have been found, both having an activation energy of approximately  $0.47 \text{ eV}$ . Such behaviour is in qualitative agreement with Lampert's theory of SCL conduction. Some deviations from this theory are accounted for by the existence of macroscopic screening length in SI-GaAs. (Author abstract) 15 refs.

**093797 EVIDENCE FOR ACCEPTOR SURFACE STATES IN GaAs PLANAR-TYPE DEVICES.** The

nature of surface states existing on a bare surface of weakly n-doped VPE (vapor phase epitaxy) GaAs layers ( $\approx 10^{14} \text{ cm}^{-3}$ ) has been investigated. Planar-type devices with large interelectrode length ( $\approx 60 \mu\text{m}$ ), have been used. In order to identify bulk effects, previous measurements (in darkness) of channel current transients resulting from backgating effects have shown the existence of the EL2 electron trap and of a hole trap (activation energy  $\approx 0.11 \text{ eV}$ ) located at the substrate-channel interface. Photoreponse measurements under illumination in the  $0.8\text{-}2 \text{ eV}$  energy range and transient channel current measurements in darkness, after switching-off the illumination (in the same energy range) have been performed. From these measurements, the existence of acceptor surface states at an energy of  $0.4 \text{ eV}$  above the valence band is demonstrated and confirmed by studying the  $\text{EL2} \rightarrow \text{EL2}^*$  photoconversion. Thermal ionization of these surface states has been evidenced experimentally. (Author abstract) 11 refs.

**093798 PERPENDICULAR TRANSPORT OF OPTICALLY GENERATED CARRIERS IN GaAs/AlGaAs QUANTUM WELL STRUCTURES.** We have calculated the transport of carriers over GaAs quantum wells embedded in an AlGaAs slab of some micrometers thickness. The carriers are generated near one surface by means of a laser beam. We have solved the Boltzmann equation using the iterative technique. The quantum wells are modeled as interfaces, where the carriers can be transmitted, reflected, or captured with probabilities  $T$ ,  $R$ , and  $W$ , respectively. The capture probability is calculated for emission of optical phonons and the modification of the initial state is taken into account in order to satisfy the condition  $R+T+W=1$ . Due to the energetic position of the transmission resonances with respect to the bottom of the conduction band in the AlGaAs the time-dependent behavior of the carrier system after a picosecond laser pulse is shown to depend sensitively on parameters like quantum well width and depth. (Author abstract) 22 Refs.

**093800 CALCULATION OF BOUND EXCITONS IN  $\text{GaAs-Ga}_{1-x}\text{Al}_x\text{As}$  QUANTUM WELL STRUCTURES.** The ground state energies of an exciton bound to a neutral donor and an exciton and biexciton bound to an ionized donor have been calculated using the density functional theory. The results are compared with experimental data. (Author abstract) 12 Refs.

Haufe, A. (Karl-Marx-Univ, Leipzig, East Ger). *Solid State Commun* v 67 n 9 Sep 1988 p 899-901.

**093801 HYDRODYNAMIC CARRIER TRANSPORT IN SEMICONDUCTORS WITH MULTIPLE BAND MINIMA.** Carrier transport equations for analysis of semiconductor devices fabricated in materials with multiple band minima, such as GaAs, are presented. An approach is taken in which the carrier density is conserved and an approximation to the distribution function in terms

of quasi-Fermi potentials, carrier temperatures, and other fixed parameters is used that satisfies the particle energy and temperature distributions for each valley in the material. A model of a GaAs MESFET, which illustrates the importance of the physical effects and achieves reasonable agreement with experiment without use of adjustable parameters, is presented as an example. 22 refs.

**093802 ELECTRONIC RAMAN SCATTERING IN QUANTUM WELLS: COUPLED LEVELS IN TILTED MAGNETIC FIELDS.** We report on a magneto-Raman scattering investigation of free and donor-bound electrons in GaAs-Al<sub>x</sub>Ga<sub>1-x</sub>As quantum wells. For fields perpendicular to the layers, the spectra show intersubband transitions of photoexcited electrons and 1s → 1s' donor excitations. Tilted fields lead to subband-Landau level and 1s'-2p<sup>+</sup> coupling. Experimental results for the latter case agree very well with variational calculations. Data on combined intersubband-cyclotron resonances at arbitrary tilt angles are accurately described by expressions valid for parabolic wells. The parabolic approach is shown to provide a good approximation in situations where coupling to higher subbands can be neglected. (Author abstract) 16 refs.

**093803 MAGNETIC DEPOPULATION OF SUBBANDS AND UNIVERSAL CONDUCTANCE FLUCTUATIONS IN QUASI-ONE-DIMENSIONAL GaAs-AlGaAs HETEROSTRUCTURES.** Narrow conducting channels have been fabricated in the two-dimensional electron gas in a GaAs-AlGaAs heterostructure, using a recently developed shallow mesa etch technique. Four-terminal high field magnetoresistance measurements at temperatures down to 2 K have been performed on samples with etched width between 8 μm and 0.5 μm. The Shubnikov-de Haas oscillations are studied, and clear evidence is presented for magnetic depopulation of 1-dimensional subbands. The data for the 0.5 μm wide channel are in satisfactory agreement with a simple analysis based on a parabolic confinement potential. Large sidewall depletion effects are found. We also observe irregular structure in the magnetoresistance. The dependence of the effects on the orientation of the magnetic field shows that the magnetoresistance arises from the orbital motion of the 2-dimensional electrons. (Edited author abstract) 15 refs.

**093804 COMPLEX BAND STRUCTURE CALCULATIONS OF THE ELECTRIC FIELD DEPENDENCE OF THE TRANSMISSION OF HOLES THROUGH A (100) GaAs/AlGaAs/GaAs BARRIER STRUCTURE.** A pseudopotential complex band structure approach is used to investigate the transmission of heavy and light holes through a (100) GaAs/AlGaAs/GaAs barrier structure in the presence of an electric field. The results can be significantly different from those obtained using a simple effective mass model. In particular, for an incident light hole there is large barrier induced mixing with the spin-split-off states which reduces the light hole transmission and excites the transmission of spin-split off states. Transmission through a quantum well structure is also considered and significant effects are seen due to the presence of resonances. (Author abstract) 10 refs.

**093805 HOT CARRIER TRAPPING IN GaAs/AlGaAs SINGLE QUANTUM WELLS WITH DIFFERENT CONFINEMENT STRUCTURES.** The trapping efficiency and dynamics of hot carriers in GaAs/AlGaAs single quantum wells with different confinement structures are investigated by photoluminescence excitation spectroscopy and picosecond luminescence spectroscopy. The trapping efficiency is highest for graded confinement structures and reaches 100% for a quantum well with a linear band gap profile of the AlGaAs. The lower trapping efficiencies in single quantum wells without additional confinement and in separate confinement heterostructures is attributed to radiative and nonradiative recombination in the AlGaAs. The trapping times are shorter than 20ps for all the different structures. (Author abstract) 5 refs.

**093806 MAGNETIC FIELD-DEPENDENT HOT CARRIER RELAXATION IN GaAs QUANTUM WELLS.** Energy loss rates are calculated for electrons, confined in a GaAs quantum well and by a magnetic field perpendicular to its plane, interacting with unconfined LO phonons. Phonon emission rates calculated are compared with the temperature decay of carriers photoexcited by a picosecond laser pulse, measured by time-resolved luminescence spectroscopy. Measured energy loss rates are much less than those calculated assuming equilibrium phonon populations. A numerical calculation of the evolution of the coupled electron and phonon systems demonstrates that this is due to the generation of non-equilibrium phonons. After a few tens of picoseconds carrier cooling is governed by phonon decay. The carrier temperature decay curve depends on the volume of phonon phase space to which the carriers are coupled, the phonon lifetime and the carrier specific heat, and is relatively insensitive to the field-dependence of the carrier-phonon scattering matrix elements and carrier density of states. (Author abstract) 12 refs.

Turberfield, A.J. (Univ of Oxford, Oxford, Engl). *Solid State Electron* v 31 n 3-4 Mar-Apr 1988, Hot Carriers in Semicond, Boston, MA, USA, Jul 20-24 1987 p 387-390.

**093807 ULTRAFAST RELAXATION OF HOT PHOTOEXCITED CARRIERS IN GaAs.** The roles of carrier-carrier interactions and nonequilibrium phonons on the ultrafast relaxation of photoexcited carriers in GaAs are examined. At low carrier concentrations, the e-h interaction is the main energy loss channel for hot electrons, while at high carrier concentrations, the e-h interaction is the primary energy loss channel. This latter result follows from the high e-h scattering rate, the screening of the e-h interaction, and the high efficiency of hole-phonon scattering through the unscreened deformation potential interaction. The electron energy-loss rates through the e-h interaction increases as the excitation energies and intensities are increased. In two-dimensional systems, the e-h interaction further complicates the problem since the transverse optical modes are driven out of equilibrium by their interaction with the holes. (Edited author abstract) 19 refs.

**093808 INITIAL RELAXATION OF PHOTOEXCITED CARRIERS IN GaAs AND GaAs QUANTUM WELLS UNDER SUBPICOSECOND EXCITATION.** After excitation by a subpicosecond pulse, we observe a slow rise of the luminescence both in GaAs and in GaAs quantum wells. By comparing the results in GaAs and InP, we show that the slow rise in GaAs and GaAs quantum wells is due to the slow return of the electrons

from the L to the Γ valley. Our results show the importance of electron-electron scattering and the inadequacy of a simple phonon cascade model at densities as low as  $5 \times 10^{16} \text{ cm}^{-3}$ . (Edited author abstract) 8 refs.

**093809 FEMTOSECOND RELAXATION DYNAMICS OF NONEQUILIBRIUM CARRIERS IN GaAs AND RELATED COMPOUNDS.** The initial relaxation of hot electrons in AlGaAs has been measured using optical correlation spectroscopy at temperatures from 300 to 10 K and a range of carrier densities. Comparison of the results shows that, at 300 K, of the carriers that leave the initially excited states within the first 50 fs, 65% scatter to the satellite valleys, 30% leave via carrier-carrier interactions including plasmon scattering, and approximately 5% scatter by LO phonon emission. (Author abstract) 5 refs.

**093811 NONEQUILIBRIUM PHONON EFFECTS ON THE TIME-DEPENDENT RELAXATION OF HOT CARRIERS IN GaAs MQW.** The existence of a large population of nonequilibrium hot phonons after an initial rapid carrier cooling in an undoped multiple GaAs quantum well structure excited by 500fs laser pulses is experimentally verified. An effective carrier depletion time is determined to be as short as 10ps. A mechanism which leads to such a short carrier depletion time is associated with hot phonon enhanced phonon-replica-emission. (Author abstract) 8 refs.

**093812 CARRIER-CARRIER INTERACTION AND INTERVALLEY TRANSFER EFFECTS ON THE ULTRAFAST RELAXATION OF PHOTOEXCITED ELECTRONS IN GaAs.** The roles of the carrier-carrier (c-c) and intervalley deformation potential interactions on the ultrafast cooling of electrons in GaAs are examined for excitation energy of 2.0 eV and in the presence of uniform 500 v/cm applied electric field, using an Ensemble Monte Carlo (EMC) approach. It is found that immediately after excitation, a significant portion of the electrons transfer to the upper valleys where they relax primarily through the emission of LO, equivalent and nonequivalent intervalley phonons. Subsequently, the electrons return to the central valley. When the electron-hole interaction is included, 70% of the electron population to return to the central valley after 2.3 ps, compared to 3.1 ps when the e-h interaction is ignored. **093815 TRANSIENT HOT-PHONON EFFECTS ON THE VELOCITY OVERSHOOT OF GaAs: A MONTE CARLO ANALYSIS.** A novel ensemble Monte Carlo algorithm has been developed to simulate nonequilibrium phonon effects in the transient and steady-state high-field conductivity of bulk n-GaAs. The interplay of the electronic intervalley transfer with the mutual drag and heating between the carriers and longitudinal optical phonons is demonstrated over a wide range of fields, temperature and carrier densities. For the moderately high doping levels of practical interest the characteristic times for a strong phonon amplification turn out to be sufficiently long to prevent a substantial interference of phonon disturbances with the onset of valley transfer during overshoot, but modifications of up to 20 percent are found for the steady-state velocity, with a gradual change from an enhancement at low fields to a comparable decrease around the maximum and negative differential part of the velocity-field characteristics. Comparable nonequilibrium-phonon effects are found for the case of negligible (i.e. remote) ionized-impurity scattering as realized in various GaAs-based heterostructures. (Author abstract) 10 refs.

Rieger, M. (Univ Graz, Graz, Austria); Koccar, P.; Bordone, P.; Lugli, P.; Reggiani, L. *Solid State Electron* v 31 n 3/4 Mar/Apr 1988 p 687-690.

**093816 HOT ELECTRON RELAXATION IN POLAR SEMICONDUCTORS.** Theoretical results are obtained for the energy-loss of hot electrons to longitudinal optical phonons in three and two dimensional semiconductor (GaAs bulk and quantum well case) systems for carrier temperatures between 25K and 200K. All the relevant physical effects (quantum statistics, dynamical screening, plasmon-phonon coupling, Landau damping, hot phonon effects and quantum-well width corrections) are included in a many-body calculation. Our theory agrees with experimental results and explains quantitatively an order of magnitude discrepancy in experimental relaxation rates in GaAs quantum wells reported by different groups as arising from a partial cancellation between plasmon-phonon mode-coupling and hot phonon effects thus resolving an important controversy in the subject. (Edited author abstract) 14 refs.

**093817 HOT ELECTRON CAPTURE IN GaAs MQW: NDR AND PERSISTENT EFFECTS.** We report the observation of negative differential resistance (N.D.R.) associated with the capture of hot carriers at low temperatures by low mobility centres in GaAs-Ga<sub>1-x</sub>Al<sub>x</sub>As multiple quantum wells. NDR occurs with threshold fields of a few hundred volts cm<sup>-1</sup>. The barrier height

over which the hot carriers are captured is directly obtained from the hot-electron PL spectra. The depth of the trapping centres are directly observed. In a p type sample, following the capture of hot carriers, a field-induced persistent conductivity state is observed. Nondestructive switching to and from this state occurs which is probably associated with the impact ionization of the captured carriers. (Author abstract) 14 refs.

**093818 ULTRAVIOLET ABSORPTION SPECTRA OF SELECTED ORGANOMETALLIC COMPOUNDS USED IN THE CHEMICAL VAPOR DEPOSITION OF GALLIUM ARSENIDE.** Ultraviolet absorption spectra and absolute absorption cross sections of trimethylgallium (CH<sub>3</sub>)<sub>3</sub>Ga, triethylgallium (C<sub>2</sub>H<sub>5</sub>)<sub>3</sub>Ga, trimethylarsine (CH<sub>3</sub>)<sub>3</sub>As, and triethylarsine (C<sub>2</sub>H<sub>5</sub>)<sub>3</sub>As have been recorded as a function of temperature. Room temperature peak absorption cross sections of 2.6×10<sup>-17</sup>, approx. 1.7×10<sup>-17</sup>, 5.6×10<sup>-17</sup>, and 4.1×10<sup>-17</sup> cm<sup>2</sup>, respectively, were obtained for the above compounds at 195.0, approx. 190.0, 201.0, and 208.5 nm. (CH<sub>3</sub>)<sub>3</sub>As and (C<sub>2</sub>H<sub>5</sub>)<sub>3</sub>As were found to be thermally stable up to 350°C, whereas (CH<sub>3</sub>)<sub>3</sub>Ga and (C<sub>2</sub>H<sub>5</sub>)<sub>3</sub>Ga began to show decomposition at approximately 300-350°C. This study resolves previous discrepancies in the absorption cross section for (CH<sub>3</sub>)<sub>3</sub>Ga, and provides data for photo-enhanced deposition studies and optical diagnostic measurements in conventional chemical vapor deposition. (Author abstract) 22 refs.

**093819 EVALUATION OF LARGE AREA HETEROSTRUCTURE MATERIAL FOR HIGH POWER LASER STRUCTURES.** Metal organic chemical vapor deposition (MOCVD) is now widely recognized as the most appropriate technology for adapting to the requirements of opto-electronic device production. We report on the development of MOCVD for the growth of two inch diameter multi-heterostructure (MH) laser wafers along with the establishment of material assessment techniques capable of evaluating the properties of large geometry structures. Electrical and optical characterization of single and multi-heterostructures have been made in order to evaluate and optimize alloy, thickness and doping uniformity. A cross-calibration exercise between various electro-optic techniques has been carried out and a high level of agreement found between measured parameters. An ability to maintain intact substrate geometry allows information to be acquired on epitaxial growth prior to processing. Oxide-isolated facet-coated stripe lasers have been fabricated from two-inch processed wafers producing high output power >20 W at 40 Å under pulsed conditions. Threshold current densities of 1 kA cm<sup>-2</sup> along with T<sub>0</sub> values of 155 K have been achieved. Far fields of 23° along with stable output power over a wide temperature range (25°-95°C) are reported. (Author abstract) 21 refs.

**093820 AlGaAs GROWTH BY OMCVD USING AN EXCIMER LASER.** AlGaAs has been grown as GaAs by laser assisted OMCVD using an excimer laser, wavelength 193 nm, and a Cambridge OMCVD reactor. Films were grown at temperatures of 450 and 500°C with the laser beam parallel to the surface and impinging onto the surface at 15° from parallel. The samples were heated by rf coils while the laser beam was perpendicular to the gas flow. Typical gas flow parameters are 12 slm of H<sub>2</sub>, 15 sccm of Ga(CH<sub>3</sub>)<sub>3</sub>, 13 sccm of Al(CH<sub>3</sub>)<sub>3</sub>, and a pressure of 250 mbar. The initial energy density of the beam at the

surface was 40 mJ/cm<sup>2</sup>, the pulse rate was 20 pps, and the growth time was 7 min. The films were analyzed by Auger electron spectroscopy for the aluminum concentration and by TEM for the surface morphology. (Author abstract) 6 refs.

**093821 SELECTIVE AREA GROWTH OF HIGH QUALITY GaAs BY OMCVD USING NATIVE OXIDE MASKS.** A study of selective area growth by atmospheric pressure organometallic chemical vapor deposition (OMCVD) using plasma-grown GaAs native oxide masks was conducted. Deposition experiments were carried out with different growth parameters to observe the variation of polycrystalline coverage on the oxide mask. With high growth temperatures or low V/III ratios, poly deposition on the mask was depleted, particularly in regions near the unmasked single-crystal areas. With the optimum conditions for GaAs growth, the polycrystalline growth was homogeneous to the single-crystal boundary, and the single-crystal GaAs areas exhibited liquid nitrogen mobilities up to 105,000 cm<sup>2</sup>/Vs. (Edited author abstract) 26 refs.

Jones, Stephen H. (Univ of Massachusetts, Amherst, MA, USA); Lau, Kei May. *J Electrochem Soc* v 134 n 12 Dec 1987 p 3149-3155.

**093822 GROWTH RATE AND UNIFORMITY OF MOCVD GaAs.** The atmospheric MOCVD of GaAs using TMG, AsH<sub>3</sub> and H<sub>2</sub> in a horizontal air-cooled reactor has been discussed and a formula of the growth rate of GaAs is derived on the basis of chemical thermodynamics and kinetics. The growth rate is linearly dependent on TMG concentration within a specified temperature range and believed to be limited by the diffusion of reaction species closely related to Ga element. The comparison of numerical calculation with the experimental data shows that this formula is in agreement with experimental results. In the formula, the relations between the growth rate, the uniformity of the epitaxial layer, and process parameters such as the velocity of gas flow, the growth temperature and the TMG mole fraction in gas flow can be seen. (Edited author abstract) In Chinese. 8 refs.

**093823 REDUCTION OF DEEP LEVEL CONCENTRATIONS IN GaAs LAYERS GROWN BY FLOW-RATE MODULATION EPITAXY.** In a modified metalorganic chemical vapor deposition, flow-rate modulation epitaxy, the growth rate of GaAs can be higher than one monolayer per cycle (0.28 nm/cycle). Ga-atoms, the number of which is up to 3 times as high as the surface site number, and arsenic are alternately supplied on the (001) GaAs substrates to grow GaAs layers. There is no surface degradation of the epitaxial layers even at a growth rate of three monolayers per cycle. In this method after Ga-atomic layers are formed, As atoms diffuse into the Ga-atomic layers to form a GaAs single crystal. In GaAs layers grown under such conditions, the concentration of the midgap level, 'EL2', is much reduced. Furthermore, photoluminescence measurement indicates that high-quality GaAs layers are grown. (Author abstract) 12 refs.

**093824 CONVERGENT-BEAM ELECTRON DIFFRACTION STUDY OF STRAIN MODULATION IN GaAs/InGaAs SUPERLATTICES GROWN BY METAL-ORGANIC CHEMICAL VAPOUR DEPOSITION.** Convergent-beam electron diffraction has been used to study strain modulation in GaAs/InGaAs super-

lattices (6% In and 2% In) in plan-view. Reflections from planes inclined to the interface of the superlattice are split with sidebands, the angular separation of which is related to the modulation periodicity. It is inferred from higher-order Laue zone lines that inclined planes on opposite sides of an interface in GaAs and InGaAs layers are rotated towards and away from the interface as a result of distortion due to coherent matching and local relaxation in regions where the GaAs substrate and buffer layer have been non-milled away. (Author abstract) 12 refs.

**093825 LATERAL GROWTH ON (110) GaAs SUBSTRATES BY METALORGANIC CHEMICAL VAPOR DEPOSITION.** Lateral growth was carried out on (110) GaAs substrates by metal-organic chemical vapor deposition (MOCVD). In the case of lateral layers extending over free GaAs surfaces, the lateral growth rate is highest in the  $[00\bar{1}]$  direction and lowest in the  $[001]$  direction; the dependences can be explained by the stability of the kink sites. In the case of lateral layers extending over  $\text{SiO}_2$  films, definite facets appear in  $[1\bar{1}1]A$ ,  $[1\bar{1}10]$ , and  $[1\bar{1}2]$  directions, and lateral layers extending in the  $[111]A$  direction show an extremely smooth surface and a plumb  $(1\bar{1}1)A$  plane at the front edge. The ratio of lateral length to thickness is 1.4, which coincides well with the ratio of monolayer space of the  $[111]$  surface to the  $\{110\}$  surface. (Author abstract) 7 refs.

Okamoto, Kotaro (Univ of Electro-Communications, Chofu, Jpn); Furuta, Mamoru; Yamaguchi, Ko-ichi. *Jpn J Appl Phys Part 2* v 27 n 3 Mar 1988 p 437-440.

**093826 ATOMIC LAYER EPITAXY OF GaAs USING SOLID ARSENIC AND  $\text{DEGaCl}$ .** ALE growth of GaAs was reported using solid arsenic and  $\text{DEGaCl}$ . An abrupt shutoff of arsenic vapor was successfully achieved and monolayer growth was obtained independent of  $\text{DEGaCl}$  partial pressure. Grown surfaces were mirror-like at growth temperatures of 400 approximately  $550^\circ\text{C}$ . Grown layers showed p-type conductivity. The carrier concentration of the grown layers was rather low compared with that reported in  $\text{DEGaCl-AsH}_3\text{ALE}$ . QMS measurements of the  $\text{DEGaCl}$  decomposition rate suggest that  $\text{DEGaCl}$  completely decomposes to GaCl before reaching the substrate, which is considered to result in lower carbon contamination. (Author abstract) 16 refs.

**093827 GROWTH AND CHARACTERIZATION OF GaAs LAYERS GROWN ON Ge/Si SUBSTRATES BY METALORGANIC CHEMICAL VAPOR DEPOSITION.** Epitaxial GaAs layers have been grown on (100) oriented Ge/Si substrates by metalorganic chemical vapor deposition. Double-crystal X-ray diffraction shows that the full width at half maximum of the (400) reflection obtained from 3  $\mu\text{m}$ -thick GaAs is as small as  $114$  arc seconds. The GaAs surface dislocation density estimated by a molten KOH study is  $4.9 \times 10^6 \text{ cm}^{-2}$ . Photoluminescence measurements show that an excitonic transition at  $1.4852 \text{ eV}$  dominates at  $4.2 \text{ K}$ . These results suggest that Ge/Si substrates are suitable for growing sufficiently high quality GaAs layers. (Author abstract) 25 refs.

Fukuda, Yukio (NTT, Applied Electronics Lab, Musashino, Jpn); Kadota, Yoshiaki; Ohmachi, Yoshiro. *Jpn J Appl Phys Part 1* v 27 n 4 Apr 1988 p 485-488.

**093828 COMPARISON OF ALTERNATE AS-SOURCES TO ARSINE IN THE MOCVD GROWTH OF GaAs.** We have investigated the use of methyl-, ethyl-, and butyl-based alkylarsine compounds as alternatives to arsine in the epitaxial growth of GaAs. These are all low vapor pressure liquids that can be handled more safely than arsine, which is stored as a high pressure gas. Films were deposited over a wide range of growth conditions ( $T_g$

=  $550\text{--}850^\circ\text{C}$ ,  $V/\text{III} = 2\text{--}20$ ) at atmospheric pressure in a horizontal MOCVD reactor. The quality of the films grown with the alkylarsine sources was limited by the presence of both carbon and donor impurities. Isotopic labeling studies using 50% enriched  $^{13}\text{C}$ -trimethylarsine provided direct evidence that the methyl groups from trimethylarsine were a major source of the carbon observed in the films. The effects of source purity and composition on the morphological, electrical and optical properties of the GaAs films will be presented. (Author abstract) 23 refs.

## Chromatographic Analysis

**093829 G.c./m.s. ANALYSES OF TRIMETHYL GALLIUM AND TRIMETHYL ALUMINIUM.** A transfer device designed to enable sampling of metalorganic chemicals from conventional 'bubblers' employed in MOCVD applications, for analysis by capillary gas chromatography in combination with mass spectrometry (g.c./m.s.) is described. Chromatographic and mass spectra data obtained from the analysis of trimethylgallium and trimethylaluminum as examples of extremes in volatility are reported. The difficulties presented by the more reactive metalorganic,  $\text{Me}_3\text{Al}$ , to the success of the analysis by g.c./m.s. are outlined. The relevance of the findings to MOCVD is discussed in terms of the information obtained concerning the presence, amounts and identities of extrinsic organic impurities. (Author abstract) 9 refs.

## Composition Effects

**093831 CONTROL COMPOSITION OF THE MELT STOICHIOMETRY IN LEC SEMI-INSULATING GaAs.** Control of the melt stoichiometry is an essential factor to obtain undoped LEC semi-insulating GaAs. Experiments have showed that the As weight loss depends on the heat processes, heating rate, the crucible and height of the boronic oxide layer. The arsenic weight loss from crucible of pyrolytic boron nitride is greater than that from a Quartz crucible. (Edited author abstract) 7 refs. In Chinese.

## Computer Simulation

**093832 MONTE CARLO PARTICLE SIMULATION FOR NDM OF GaAs.** Monte Carlo particle simulation method has been used to study the negative differential mobility of electrons in the GaAs conduction energy band. The initial states of electrons are proposed to be located in the 64 band according to Maxwell distribution. Electrons drifted along the electric field encounter polar optical or acoustic phonon scattering among valleys or within valleys. It is supposed that the directional velocity of electrons after scattering is eliminated. (Edited author abstract) In Chinese. 6 refs.

**Contacts See Also ELECTRIC CONTACTS—Fabrication.**

**093833 DEGRADATION OF SCANNED-ELECTRON-BEAM ALLOYED OHMIC CONTACTS ON n-GaAs.** Degradation of scanned-electron-beam (SEB) and furnace-alloyed Au-Ge-Ni Ohmic contacts to n-type GaAs with time, above room temperature, has been studied with and without current flow through the contacts. The degradation is characterized in terms of contact resistivity, source-to-drain resistance  $R_{sd}$ , and more stable than surface-alloyed contacts when aging is performed at temperatures below  $300^\circ\text{C}$  without current flow, and the smooth surface morphology of the SEB-alloyed contacts is lost when they are aged above  $300^\circ\text{C}$ . SEB-alloyed contacts show a overall reducing contact resistivity with aging time. In the case of gradual degradation of contacts due to current flow above room temperature, for typical GaAs field-effect-transistor contact structures, the SEB-alloyed contacts do not show any performance advantage over furnace-alloyed contacts. (Author abstract) 25 refs.

**093834 BIHOLE IN QUANTUM WELL STRUCTURES.** In  $\text{GaAs-Ga}_{1-x}\text{Al}_x\text{As}$  many quantum well structures or superlattices the top valence subband VBI of size quantization is heavy-hole-like HH1 and the effective mass  $m_1$  is positive. The second valence subband VB2 has a heavy-hole - HH2 or light-hole - LH1 character in dependence on the barrier and well layer thicknesses and the composition  $x$ . The effective mass  $m_2$  in VB2 is negative and the condition for bihole formation  $m_1 > |m_2|$  is fulfilled. The binding energy if the bihole is calculated. The bihole formation due to light absorption is studied. The oscillator strengths in the cases of inter- and intrasubband transition of holes succeeded by bihole formation are obtained. (Author abstract) 13 refs.

**093835 LATTICE DYNAMICS OF GaAs/AlAs SUPERLATTICES.** We report on the results of three-dimensional shell model calculations of GaAs/AlAs superlattice phonon frequencies and eigenvectors. Their dependence on direction and magnitude of the wavevector is investigated. Among others we find the occurrence of acoustical (Lamb- and Love-like) guided and optical (Fuchs-Kliwer-like) interface phonons for wavevectors perpendicular to the layer normal; for wavevectors parallel to the normal there are folded and confined phonons. For the folded phonons the ionic displacements can be described by continuously matched sine and cosine functions. An effective wavevector can be attributed to the confined phonons. With this wavevector Raman data in

superlattices are reevaluated and compared with recent high-accuracy neutron scattering data for bulk GaAs. (Author abstract) 18 refs.

**093836 TRANSMISSION ELECTRON MICROSCOPY STUDY OF DEFECTS IN Sn-DOPED GaAs FILMS GROWN BY MOLECULAR BEAM EPITAXY.** Films of GaAs, heavily doped with Sn, which have been grown by molecular-beam epitaxy are found to contain single-crystal Sn particles situated in the near surface region of the epilayer GaAs. The morphology and chemical composition of the particles have been examined by using cross-section transmission electron microscopy combined with energy-dispersive X-ray spectroscopy. Different growth conditions were used to study the Sn-particle formation and high-resolution transmission electron microscopy was used to investigate microstructures. The observations are discussed in terms of several models previously proposed for these phenomena. (Author abstract) 24 refs.

**093838 ON THE NATURE OF THE MAIN MID-GAP DONOR LEVEL EL2 IN GaAs.** In order to shed some light on the configuration of EL2 in GaAs, the authors summarize its characteristics including electrical, optical, magnetic, chemical and crystallographic properties. On the basis of this knowledge they suggest that the nomenclature EL2 be restricted to a deep donor level that can meet three important requirements simultaneously, i.e., stoichiometric relation, dislocation density dependence and photoquenching behavior. In this way, the complication arising from the presence of the EL2 may be alleviated. (Edited author abstract) In Chinese. 70 refs.

**093839 SINGLE STACKING FAULTS IN HIGH-STRESS DEFORMED SEMI-INSULATING GaAs.** Single intrinsic stacking faults in semi-insulating undoped GaAs have been studied by transmission electron microscopy. The crystals were deformed at room temperature by uniaxial compression and under hydrostatic pressure. It is shown that the stacking faults are produced by the dissociation of  $60^\circ(\beta)$  dislocations under very high stress ( $\tau \approx 0.75$  GPa). The partial dislocations bounding the stacking faults are systematically  $30^\circ(\beta)$  in character. These observations are consistent with the classification of mobilities of partial dislocations that had been previously established when studying deformation microtwins in the same material:  $30^\circ(\beta) < 30^\circ(\alpha) < 90^\circ(\alpha$  or  $\beta)$ . (Author abstract) 12 refs.

**093840 DISLOCATION VELOCITY MEASURE-**

**MENTS IN SEMI-INSULATING In-DOPED GaAs.** The mean velocities of  $\alpha$ ,  $\beta$  and screw dislocations in doped GaAs have been determined by X-ray topography. Although the velocities of  $\beta$  dislocations were found to be nearly equal to those measured in undoped material, the velocities of  $\alpha$  and screw dislocations were lower. The activation energies for dislocation motion were found to be approximately the same as in undoped material, except for temperatures higher than  $400^\circ\text{C}$  and values of the resolved shear stress,  $\sigma$ , less than 10 MPa. In this range, the mobilities of  $\alpha$  and screw dislocation were more severely reduced and were time-dependent. We suggest that these different effects are related to a selective interaction between the dopant (In) and  $\alpha$  partials. (Author abstract) 11 refs.

**093841 ARSENIC ANTISITE DEFECTS IN GaAs AND GaP: PSEUDO JAHN-TELLER EFFECT AND TEMPERATURE DEPENDENCE OF THE HYPERFINE CONSTANT.** Electron paramagnetic resonance experiments on arsenic antisites in GaAs and GaP show that the hyperfine constant decreases sharply with temperature. It is demonstrated here that this effect can be quantitatively explained by a pseudo Jahn-Teller effect between the ground ( $A_1$ ) and excited ( $T_2$ ) electronic states of the defect. This also results in a softening of some local force constant. The relation to the case of off-center impurities is discussed. (Author abstract) 15 refs.

**093842 DISLOCATION REDUCTION IN GaAs ON Si BY THERMAL CYCLES AND InGaAs/GaAs STRAINED-LAYER SUPERLATTICES.** The etch-pit density of epitaxial GaAs layers grown on Si was significantly reduced by using the technique of growth interrupt and thermal cycles (in situ TC) followed by growth of  $\text{In}_{0.1}\text{Ga}_{0.9}\text{As}$ /GaAs strained-layer superlattices (SLs). The etch-pit density of  $1.4 \times 10^6 \text{ cm}^{-2}$  (density of small pits by molten KOH etching) was achieved in 3.5  $\mu\text{m}$ -thick GaAs epilayers. It was also found that the effect of SLs on dislocation reduction was more enhanced by combining with the in situ TC process than the effect when SLs were used by themselves. **093844 ON THE METASTABILITY OF THE EL2 DEFECT IN PLASTICALLY DEFORMED GaAs.** DLTS spectra and transients of photocapacitance quenching under  $\lambda = 1.06 \mu\text{m}$  photoexcitation of the EL2 defect were investigated in GaAs crystals subjected to plastic deformation. The concentration of EL6 traps increased, and the quenching became slower and non-exponential, after the sample deformation. It is argued that the deformation-induced EL6 traps in the vicinity of EL2 open a new channel for the deexcitation of EL2: phonon assisted electron tunneling from EL2 to EL6, which diminishes the transformation rate of EL2 into the metastable state. EL6 is assigned to the isolated  $\text{As}_{\text{Ga}}$  antisite defect. (Author abstract) 28 refs.

**093845 ANALYSIS OF THERMALLY STIMULATED CURRENT SPECTROSCOPY IN SEMI-INSULATING GaAs. I. INITIALIZATION.** The operation of improved thermally stimulated current (TSC) spectroscopy is described and analyzed. This method is suited for studying defects in semi-insulating (SI) GaAs at liquid-helium temperatures. This paper, the first in a series, presents an analysis of the first half process of TSC, that is, initialization, which consists of three stages: carrier generation, transport, and trapping. The initialization is analyzed in terms of such parameters as electrode spacing, biasing voltage and polarity, excitation light energy and dose, and temperature. The analysis leads to new methods of determining the cross section of a deep level trap. From the photocurrent transient, the cross section was estimated for the dominant trap(s) as  $5 \times 10^{-15} \text{ cm}^2$ . Another method offers an estimation for nondominant trap levels. **093847 INFLUENCE OF SUBSTRATE DEFECTS ON THE STRUCTURE OF EPITAXIAL GaAs GROWN BY MOCVD.** GaAs layers were grown by MOCVD under 'optimum' conditions on substrates containing structural defects which are most commonly encountered in variously doped, LEC and HB grown, bulk GaAs crystals. The structure of the homo-epitaxial samples was investigated by sequent DSL photoetching. Dislocations of various types were generally found to propagate in a one-to-one relation from the substrate into the epilayer. The same was observed for twins. Impurity inhomogeneities in the substrate, such as growth striations and extended atmospheres around grown-in dislocations, have no noticeable influence on the epilayer structure. Microdefects, both in the bulk matrix and along grown-in dislocations, can produce a multiple of epilayer dislocations. Heavily indium-doped substrates lead to the formation of networks of misfit dislocations. (Author abstract) 27 refs.

**093848 ANTISITE DEFECTS IN PLASTICALLY-DEFORMED GaAs: AN ALTERNATIVE ANALYSIS.** A revision is presented of the accepted view that the observed increase in electron paramagnetic resonance (EPR) with plastic deformation in GaAs is due to the generation of As antisite defects. It is proposed instead that only compensating deep acceptor defects are generated. The increase of the EPR signal from As antisites can then be attributed to the compensation of the neutral As antisites that were already present in the as-grown GaAs. The nonquenching extrinsic absorption can be attributed to the acceptors. The same analysis suggests that in the case of electron and neutron irradiation, both acceptors and As antisites are generated. These proposals succeed in

eliminating some recently imposed complexities in the relationship between As antisites and EL2. (Author abstract) 11 refs.

**093850 INTERFACE STUDY ON GaAs-ON-Si BY TRANSMISSION ELECTRON MICROSCOPY.** A correlation between the surface and interface defects in GaAs-on-Si structures was examined by KOH etching and transmission electron microscopy. Line-shaped etch pits revealed on the GaAs-on-Si (100) were attributed to twins produced at the interface. This twin generation was avoided by off-setting the substrate orientation. An alternative for this is the application of an additional heat treatment after the GaAs buffer layer is grown. In this case, the twin propagation ends on the buffer layer. (Author abstract) 10 refs.

**093851 ELECTRON PARAMAGNETIC RESONANCE OF ISOLATED  $As_{Ga}$  + ANTISITE DEFECT IN NEUTRON-TRANSMUTATION DOPED SEMI-INSULATING GaAs.** The isolated  $As_{Ga}$  antisite defect produced by the neutron-transmutation doping in semi-insulating GaAs was studied using the electron paramagnetic resonance technique. The results show that the optically induced quenching of the isolated  $As_{Ga}$  + antisite defect is quite different from that of the EL2 center. Illumination with white light seems to always reduce the electron paramagnetic resonance spectrum suggesting that depopulation of the EL2 center does not introduce a noticeable change in the  $As_{Ga}$  + antisite concentration. (Author abstract) 11 refs.

**093852 EXPLORATION ON THE NATURE OF HOLE TRAPS A AND B IN LPE n-TYPE GaAs.** Two series of experiments have been performed on hole traps A and B in LPE GaAs grown under arsenic-deficient conditions and a comparison has been made between the concentration of A and B and the diffusion coefficient of  $V_{Ga}$  within the temperature range 770-870 degrees C. The results lead us to understand that hole traps A and B are related to  $V_{Ga}$  and  $V_{As}$  respectively and they are all related to  $V_{Ga}$ . These results are supported by our previous experiments as well as those of Prints et al., and Hasegawa and Majerfeld. Finally, the results are discussed on the basis of our thermochemical model. (Author abstract) 8 refs.

**093853 REDISTRIBUTION OF EL2 IN UNDOPEd SEMI-INSULATING GaAs DURING ANNEALING UNDER ARSENIC OVERPRESSURE.** The variations of the EL2 concentration in undoped semi-insulating (SI) GaAs crystals with arsenic pressure,  $P(As_2)$ , during high-temperature annealing have been investigated using infrared absorption measurements at 1.1  $\mu m$ . It is found

that the variations can be divided into two types within a range of  $P(As_2) < 2$  atm, beyond which the EL2 concentration, not varying with  $P(As_2)$ , approached an apparently saturated value which is correlated with the stoichiometry of as-grown crystals. An improvement on the uniformity of EL2 distributions is achieved after annealing. These results are in agreement with an analysis proposed in a previous paper. (Author abstract) 11 refs.

**093854 ROLE OF EL2 CENTRES IN INFRA RED IMAGES OF DEFECTS IN GaAs MATERIALS.** Careful measurements of the changes induced by photoquenching in the infrared transmission image of GaAs wafers at Liquid Nitrogen temperature shows an important enhancement of the mean light level and disappearance of the usual fourfold feature; but it also shows that the contrast of the pattern (cell structure) is not affected at all. The contribution of EL2 centres to the image is questioned; it is deduced from these results that photoquenchable EL2 centres are slightly more abundant in the cells than in the walls. In large cell materials an intermediate zone is found surrounding the cells and containing higher EL2 densities. This sheds new light on the role of the dislocations; these results are discussed and compared with etching and luminescence images. (Author abstract) 34 refs.

Fillard, Jp (Univ des Sciences et Techniques du Languedoc, Montpellier, Fr); Montgomery, P.; Gall, P.; Asgarinia, M.; Bonnafe, J. *Jpn J Appl Phys Part 1* v 27 n 3 Mar 1988 p 384-388.

**093855 PREDICTION OF EQUILIBRIUM DEFECT CONCENTRATIONS IN GaAs AND ZnSe.** We use the local density approximation within a self-consistent pseudopotential and pseudatomic-orbital scheme to predict equilibrium point defect concentrations in semiconductors and their dependence on stoichiometry, temperature and Fermi level. We compare and contrast the native defects expected in GaAs (III-V) with those in ZnSe (II-VI). We find in stoichiometric p-type material that the dominant defect in GaAs is the cation on anion antisite defect, whereas the interstitial cation defect is dominant in ZnSe. The prominence of interstitials in p-type ZnSe tends to self-compensate the material since  $Zn_i$  is a double donor. We also demonstrate how extrinsic impurities may affect native defect concentrations by considering as an example the Zn impurity in GaAs. (Author abstract) 10 refs.

Jansen, Robert W. (Arizona State Univ, Tempe, AZ, USA); Sankey, Otto F. *Solid State Commun* v 64 n 2 Oct 1987 p 197-201.

**093856 COMPARISON OF DEEP LEVEL DEFECTS IN OMVPE GaAs LAYERS GROWN ON VARIOUS GaAs SUBSTRATE TYPES.** In order to obtain epitaxial GaAs layers with a low enough defect concentration for an analysis of process induced impurities and defects, undoped OMVPE layers were grown on different substrate types. Deep level transient spectroscopy (DLTS) showed that the epitaxial layers grown on all substrate types contained the EL2 electron trap in concentrations of about  $1 \times 10^{14}/cm^3$ . Apart from the EL2, layers grown on semi-insulating substrates contained no electron traps in concentrations above  $10^{11}/cm^3$ , while layers grown on most n+ and p+ substrates contained electron and hole traps in concentrations of well above  $10^{13}/cm^3$ . It was therefore concluded that the choice of the proper substrate type when attempting to grow epitaxial layers with a low defect concentration is of the utmost importance. (Author abstract) 13 refs.

**093857 POINT DEFECTS IN GaAs STUDIED BY CORRELATED POSITRON LIFETIME, OPTICAL, AND ELECTRICAL MEASUREMENTS.** Positron life-

time measurements were used in combination with optical (infrared absorption, photoluminescence, and photoreflection) and electrical (Hall and resistivity) investigations to study native point defects and their complexes in as-grown GaAs crystals. In undoped n-type GaAs which contains  $2 \times 10^{16} cm^{-3}$  EL2<sup>+</sup> centres strong positron trapping by a vacancy-type defect is detected. The point defect is discussed as a vacancy in the As sublattice appearing in a neutral or negative charge state. A specific positron trapping rate of  $6 \times 10^{10} s^{-1} cm^{-3}$   $s^{-1} MIN^{-1}$  ( $3 \times 10^{14} s^{-1} MIN^{-1}$ ) is estimated from comparison of electrical and positron lifetime parameters and by identifying the compensating centres in heavily doped n-type GaAs. The number of grown-in vacancies is discussed. Temperature dependent studies indicate a change in the nature of the dominating positron trap at low temperatures. Annealing experiments are discussed as a compensation of vacancies around 500 °C. (Edited author abstract) 54 Refs.

**093858 EL2<sup>+</sup> DISTRIBUTION IN THE VICINITY OF DISLOCATIONS IN GaAs-In MATERIALS.** We have recently shown that, contrary to the well-reputed opinion, the EL2<sup>+</sup> centers in GaAs undoped materials are not especially concentrated on dislocations; the cell pattern, in particular, does not disappear after photoquenching at Liquid Nitrogen Temperature. In this paper we complete this study with details of the EL2<sup>+</sup> densities in the vicinity of individual dislocations in GaAs-In materials. Laser Scanning Tomography and Infra Red Transmission images are analyzed complementarily. Grown-in axial dislocations appear to be surrounded by a wide EL2-rich cylindrical zone, whereas the dislocation itself is not to be considered as a large reservoir of gettered EL2 centers. (Author abstract) 13 Refs.

**093859 DEEP LEVEL IN SEMI-INSULATING LIQUID ENCAPSULATED CZOCHARALSKI-GROWN GaAs.** Photo-induced transient spectroscopy (PITS) was performed on various heat-treated samples of semi-insulating liquid encapsulated Czochralski-grown GaAs. Seven deep levels at 0.57, 0.52, 0.42, 0.36, 0.27, 0.22 and 0.18 eV were observed. These levels can be identified with levels seen using other deep-level techniques and a variety of crystal growth and sample preparation techniques. The levels at 0.52, 0.42 and 0.36 eV can be annealed out by heat treatment. These levels therefore seem to be associated with structural defects rather than impurities. (Author abstract) 11 Refs.

## Deformation

**093869 PHOTOSTIMULATED ENHANCEMENT OF DISLOCATION GLIDE IN GALLIUM ARSENIDE CRYSTALS.** The effect of illumination on the plastic properties of gallium arsenide crystals was studied experimentally. The illumination reduces the plastic flow stress. The phenomenon is referred to as the negative photoplastic effect. The NPPE and the mean velocity of dislocations were investigated as functions of temperature, stress, and strain as well as intensity and wavelength of the exciting light. Based on the analysis of experimental results a physical model is proposed. (Edited author abstract). 33 Refs.

**093870 AMPHOTERIC DOPING IN SI-IMPLANTED UNDOPED OR IN-DOPED CZOCHRALSKI GaAs.** We have studied the conditions causing amphoteric doping in Si-implanted Czochralski GaAs by photoluminescence and Hall effect measurements. Wafers of either undoped or In-doped GaAs were implanted and capped with either  $SiN_x$  or  $SiO_x$  before the activation anneal. Localized, strong amphoteric doping was observed only in  $SiN_x$  capped In-doped wafers. In all other annealed wafers only donor activity was detected. This effect is explained by the point defect reactions due to the presence of In and the interaction of the GaAs with the capping material during annealing. (Author abstract) 7 refs.

**093871 SIMPLE OPEN-TUBE Zn-DIFFUSION TECHNIQUE FOR GaAs AND AlGaAs.** This paper will describe a simple open-tube diffusion technique of Zn into GaAs and AlGaAs in a  $N_2$  ambient using a granular solid source of ZnGaAs alloy. Resulting carrier concentration profiles for both GaAs and AlGaAs are shown and discussed. Selective area diffusion has been performed in both of these materials using plasma-enhanced chemical vapor deposited (PECVD)  $Si_3N_4$  and sputtered Si diffu-

sion masks. Enhanced lateral diffusion along the mask-semiconductor interface for the above two diffusion masks are also discussed. 12 refs.

**093872 GROWTH AND CHARACTERIZATION OF GaAs DOPING SUPERLATTICES.** The paper reports on doping superlattices and measurements of material parameters. The authors discuss the properties of the effective bandgap of GaAs doping superlattices grown by molecular beam epitaxy. The GaAs structure consists of a periodic sequence of thin n-type (Si-doped) and p-type (Be-doped) layers with uniform doping concentration and can be considered as the structure of several p-n junctions connected in series. The films were grown under As-rich conditions at 530-600°C. The photoluminescence at low temperature (4.2K) was measured for a number of NIPI structures with various layer thickness and doping concentrations. (Edited author abstract) In Chinese. 5 refs.

**093874 COMPLEX COMPENSATION OF Ge PULSE-DIFFUSED INTO GaAs.** The compensation of Ge pulse-diffused into high-purity epitaxial GaAs from a thin elemental source using rapid thermal processing has been investigated. A comparison of SIMS and differential Hall effect measurements shows that the resulting  $n^+$ -doped layers are highly compensated, with atomic Ge concentrations of  $10^{21}$ - $10^{22} cm^{-3}$ , but free electron concentrations of only approx.  $1 \times 10^{18} cm^{-3}$ . In contrast to the case where Ge is introduced during crystal growth or by ion implantation,  $Ge_{Ga}$  donors are not compensated by  $Ge_{As}$  acceptors when Ge is pulse-diffused into GaAs. Photoluminescence spectroscopy shows that  $Ge_{Ga}$  donors are compensated by  $V_{Ga}$  acceptors rather than  $Ge_{As}$  acceptors. At low diffusion temperatures, Ga vacancies are formed as Ga rapidly diffuses into the Ge layer. (Edited author abstract) 19 refs.

**093876 CALCULATION OF THE HOMOGENEITY RANGE OF TIN-DOPED GALLIUM ARSENIDE.** A calculation of the homogeneity range of tin-doped gallium arsenide is performed by the method of quasi-chemical reactions. It is shown that the introduction of tin into gallium arsenide leads to a narrowing of the low-temperature boundaries of the homogeneity range on both the Ga excess side and the As excess side. The results of the calculation are in good agreement with experimental data showing that doping gallium arsenide with tin leads to an intensification of the decomposition of a solid solution of gallium in gallium arsenide. In Russian. 17 refs.

**093877 FORMATION OF HETEROGENEITIES IN NUCLEAR-DOPED SPECIMENS OF GaAs AND InAs.** Investigations were conducted into the mechanics of formation of heterogeneities in nuclear-doped specimens of GaAs and InAs. It is shown that the nuclear doping method greatly increases (2-5 times for GaAs and 4-10 times for InAs) the homogeneity of doping in the cross section of single crystals. The relatively higher heterogeneity of nuclear-doped gallium arsenide in comparison with nuclear-doped indium arsenide is caused by the higher degree of compensation determined by residual acceptor defects and can be reduced to around 1-2% if the degree of compensation is reduced to  $K \leq 0.2$ . (Author abstract) 11 refs.

**093878 Sn INCORPORATION IN GaAs BY MOLECULAR BEAM EPITAXY.** The characteristics of heavily Sn-doped GaAs grown by molecular beam epitaxy are investigated. The free carrier concentration saturates at  $1 \times 10^{19} \text{ cm}^{-3}$  for a growth temperature of  $600^\circ\text{C}$  and at  $2 \times 10^{19} \text{ cm}^{-3}$  for  $400^\circ\text{C}$ . In the saturation region for  $600^\circ\text{C}$ , the concentration of incorporated Sn atoms increases with increasing doping concentration. SIMS and electrical characterizations show that the excess Sn atoms are incorporated into GaAs as neutral impurities. The formation of Sn-rich 3D islands does not occur on the GaAs surface at doping concentrations up to around  $3 \times 10^{19} \text{ cm}^{-3}$ , which is much higher than the previously reported critical doping concentration of  $1 \times 10^{19} \text{ cm}^{-3}$ . (Author abstract) 8 refs.

**093879 SPECTRAL SHIFT OF PHOTOLUMINESCENCE OF HIGHLY DOPED GaAs EPITAXIAL LAYERS GROWN BY MOCVD.** The photoluminescence spectra of Se-doped and Si-doped GaAs epitaxial layers grown by metalorganic chemical vapor deposition (MOCVD) were measured and compared. The spectral shift of Se-doped samples changes only with the carrier concentration, which can be explained by the Moss-Burstein shift, while that of Si-doped samples depends not only on the carrier concentration but also on growth rates and V/III mole fractions. It became apparent from x-ray diffraction that the lattice constant began to decrease in highly Si-doped layers and that the anomalous spectral shifts are caused by the lattice compression originating from a high density of  $[\text{Si}_{\text{Ga}}\text{Si}_{\text{As}}]$  pairs incorporated in highly Si-doped layers. (Author abstract) 12 refs.

**093881 HEAVILY Sn-DOPED GaAs BUFFER LAYERS FOR AlGaAs/GaAs HBTs.** The Sn atom profile in MBE grown GaAs with a buried, heavily doped layer was characterized using SIMS analysis. Sn carryforward was prevented by decreasing either the growth temperature or doping concentration. Bulk resistivity of  $0.0006 \Omega \cdot \text{cm}$  with a free carrier concentration of  $1 \times 10^{19} \text{ cm}^{-3}$  and specific contact resistance of  $1.6 \times 10^{-7} \Omega \cdot \text{cm}^2$  were obtained with samples grown at  $600^\circ\text{C}$ . To confirm the feasibility of the heavily Sn-doped buffer layer, an Al-GaAs/GaAs heterojunction bipolar transistor was fabricated. A current gain of 120 and base-collector junction breakdown voltage of 16 V were obtained. (Author abstract) 16 refs.

**093883 INFLUENCE OF LASER FLUENCE AND DOPANT GAS PRESSURE ON PROPERTIES OF PHOTOCHEMICAL DOPING OF Si INTO GaAs USING XeCl EXCIMER LASER.** Silicon doping of GaAs has been performed with the combination of pulsed XeCl excimer laser (wavelength: 308 nm) and silane gas ( $\text{SiH}_4$ ). Sheet resistances and depth profiles of the Si-doped GaAs as the functions of laser fluence, the number of laser pulses and gas pressure have been measured in order to make clear the relation between properties of doped GaAs and irradiation conditions. The secondary ion mass spectroscopy (SIMS) has revealed that the depth of Si in GaAs is limited in such a very shallow region (30-110 nm) that might be controlled easily by irradiation conditions. The efficiency for carrier generation of Si in GaAs with laser fluence is discussed. (Author abstract) 10 refs.

**093884 FUNDAMENTAL STUDIES AND DEVICE APPLICATION OF  $\delta$ -DOPING IN GaAs LAYERS AND IN  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ /GaAs HETEROSTRUCTURES.** The confinement of donor and acceptor impurities to an atomic plane normal to the crystal growth direction, called  $\delta$ -doping, is important for the fabrication of artificially layered semiconductor structures. The implementation of  $\delta$ -function-like doping profiles by using Si donors and Be acceptors generates V-shaped potential wells in GaAs and  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  with a quasi-two-dimensional (2D) electron (or hole) gas. In this review we consider three areas of fundamental and device aspects associated with  $\delta$ -doping: (i) the prototype structure of  $\delta$ -doping formed by a single atomic plane of Si donors in GaAs; (ii) GaAs sawtooth doping superlattices, consisting of a periodic sequence of alternating n- and p-type  $\delta$ -doping layers equally spaced by undoped regions; and (iii) the confinement of donors (or acceptors) to an atomic (001) plane in selectively doped  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ /GaAs heterostructures. 27 refs.

**093889 STUDY ON THE DECREASING GRADIENT DISTRIBUTION OF IMPURITIES IN GaAs EPITAXIAL LAYER.** In this paper the preparation of GaAs by a liquid phase epitaxial process is described. It is necessary that the longitudinal doping profile of the epitaxial layer for a hyperabrupt junction should be in a decreasing gradient form. The decreasing gradient is related to various forms of doping profiles and different values of  $\gamma$  can be obtained from the experimental results. In general,  $\gamma$  varies in the range of 0.6 to 2. Material produced by this method has been used to fabricate a hyperabrupt junction GaAs tuning varactor whose break-

down voltage is  $V_B=25-60V$  and ratio of capacitance variation  $C_{j0}/C_{j0(B)}$  is 10-12. (Edited author abstract). 1 Ref. In Chinese.

**093890 SILICON AND INDIUM DOPING OF GaAs: MEASUREMENTS OF THE EFFECT OF DOPING ON MECHANICAL BEHAVIOR AND RELATION WITH DISLOCATION FORMATION.** The effect of indium and silicon doping on dislocation formation in GaAs single crystals has been studied experimentally using dynamic compression tests and indentation rosettes. By direct measurements of the critical resolved shear stress (CRSS) in temperature range from 400 to 1100°C using dynamic compression tests, we found that at the melting point, the critical resolved shear stress of GaAs is twice that of undoped GaAs. More recent measurements show that at high temperatures ( $T \geq 1000^\circ C$ ) the critical resolved shear stress of silicon-doped crystals is lower than that of undoped GaAs. Well-defined indentation rosettes were obtained at high temperatures from a Vickers indenter using small loads. Analysis of such rosettes confirm that the mechanical behavior of the GaAs crystals is not drastically affected by the presence of dopants. Reduction of dislocation densities in doped crystals is attributed to modifications introduced by the dopant in the equilibrium concentration of native defects at the melting point (particularly gallium and arsenic vacancies). (Author abstract) 22 refs.

**093891 VACANCY COMPLEXES IN Cr-DOPED GaAs.** Cr-doped semi-insulating GaAs has been investigated by means of positron lifetime spectroscopy. In as-grown GaAs the dominant positron trap is a  $Cr_{Ga} \cdot V_{As}$  complex. Upon annealing the concentration of this complex increases around 260°C and then decreases at temperatures higher than 500°C. No vacancy agglomeration took place. In low temperature (130 K)  $e^-$ -irradiated (28 MeV) Cr-GaAs, di- and trivacancies were observed together with the gallium antisite,  $Ga_{As}$ . (Author abstract) 10 refs.

Mascher, P. (Univ of Winnipeg, Winnipeg, Manit, Can); Kerr, D.; Dannafer, S. *J Cryst Growth* v 85 n 1-2 Nov 1 1987, Amer Cryst Growth 1987, Proc of the Seventh Amer Conf on Cryst Growth, Monterey, CA, USA, Jul 12-17 1987 p 295-299.

**093892 DIFFUSION OF Ge IN GaAs AT  $SiO_2$ -ENCAPSULATED Ge-GaAs INTERFACES.** The diffusion of Ge in semi-insulating GaAs was investigated for annealing temperatures in the range 650-800°C. The samples consisted of electron-beam or metalorganic chemical-vapour deposition deposited Ge-GaAs interfaces encapsulated with  $SiO_2$ . Ge diffusion profiles, measured with secondary-ion mass spectroscopy (SIMS), had a characteristic plateau and steep slope at the diffusion front, similar to those obtained for Si and Sn diffusion at  $SiO_2$ -encapsulated GaAs. A new model that eliminates the necessity for paired-Ge diffusion was introduced. It proposed that dissociation and out-diffusion of GaAs into the  $SiO_2$  produced a nonequilibrium flux of vacancies into the GaAs. Calculated profiles using a position-dependent Ge diffusion coefficient were shown to fit the SIMS data independent of the type of Ge diffusing species, whether single ions or pairs. (Edited author abstract) 13 refs.

**093893 HIGH DENSITY FEMTOSECOND EXCITATION OF NONTHERMAL CARRIER DISTRIBUTIONS IN INTRINSIC AND MODULATION**

**DOPED GaAs QUANTUM WELLS.** We investigate the dynamics of non-thermal carrier distributions in undoped and modulation doped GaAs quantum well structures (layer thickness  $\approx 100$  Angstrom) with near band-gap-resonant intense femtosecond light pulses. We study selectively the carrier-carrier scattering process up to very high densities and carry out the optical investigation of non-thermal carrier generation in the presence of a thermalized Fermi-sea of electrons. In undoped quantum wells we find a reduction of the thermalization time from about 100 fs to about 30 fs as the photocarrier density increases from  $N_{eh} \approx 2 \times 10^{10} \text{ cm}^{-2}$  to  $\approx 10^{12} \text{ cm}^{-2}$ . The thermalization time is found to be sensitive to background doping with excess electrons in modulation doped samples. (Edited author abstract) 13 refs.

**093894 PRESSURE-DEPENDENT STUDIES OF THE DX CENTRE IN Si- AND Sn-DOPED  $n^+$ -GaAs.** Shubnikov-de Haas and persistent photoconductivity measurements are used to study the effect of hydrostatic pressure on the free electron concentration, mobility, and the occupancy of the DX centre in MBE grown  $n^+$ -GaAs heavily doped with either Si or Sn. The results show that the DX centre produces a resonant donor level between the F- and L- conduction band minima at a concentration comparable with the doping level. The position and occupancy of the DX centre are calculated using Fermi-Dirac statistics. For the Si-doped samples comparison with local vibrational mode measurements indicate that the DX level can be identified with  $Si_{Ga}$ . (Author abstract) 20 refs.

**093896 ETUDE DU DOPAGE RESIDUEL DE GaAs,  $Ga_{1-x}Al_xAs$  ET  $Ga_{0.47}In_{0.53}As$  EPITAXIES PAR EJM-OM.** [Study of Residual Doping of GaAs,  $Ga_{1-x}Al_xAs$ , and  $Ga_{0.47}In_{0.53}As$  by MOMBE]. GaAs,  $Ga_{1-x}Al_xAs$  and  $Ga_{0.47}In_{0.53}As$  layers were grown by metal organic molecular beam epitaxy (MOMBE) using triethyl-III sources for group III elements and a solid arsenic source. The net carrier concentration of the undoped layers was measured by Hall effect, and its dependence on growth temperature  $T_S$ , source V/source III flux ratio R and alloy composition was investigated. Low residual doping level in the range  $10^{15} \text{ cm}^{-3}$  could be achieved in GaAs (p type) using low  $T_S$  and high flux ratio R, and in  $Ga_{0.47}In_{0.53}As$  (n type), using opposite growth conditions. For  $Ga_{1-x}Al_xAs$ , an exponential dependence of the net carrier concentration x was observed. (Author abstract) 2 refs. In French.

**093897 CARACTERISATION PAR CATHODOLUMINESCENCE ET MICROSCOPIE ELECTROACOUSTIQUE DE L'INCORPORATION DES DOPANTS DANS GaAs et  $Ga_{0.28}Al_{0.19}In_{0.53}As$ .** [Characterization by Cathodoluminescence and Electroacoustic Microscopy of Dopant Incorporation in GaAs and  $Ga_{0.28}Al_{0.19}In_{0.53}As$ ]. The evolution of the near band edge and deep level cathodoluminescence emissions and of the electron acoustic signal is used to study the dopant (Be, Si) incorporation as function of growth conditions. For each material, dopant, and growth condition, a threshold doping level can be defined. Above this threshold level, the impurities are incorporated in nonelectrically active sites. All the measurements are used for a better understanding of the incorporation mechanism, especially for high doping levels. (Author abstract) 3 refs. In French.

## Economics

**093898 GaAs: BUMPY ROAD.** Gallium arsenide facilities investments have been made by numerous firms. Some within the industry have noted that the entire foreseeable market for GaAs devices and circuits could well be supplied by one or two firms, leaving the large remainder representing so much overcapacity. The fact that most of these facilities willingly accept outside work reinforces this conclusion. This article provides a perspective gained from a sampling of GaAs firms and users, a description of the business from their viewpoints. 7 refs.

**093900 RESISTIVITY AND HALL-EFFECT TOPOGRAPHY ON PHOTOEXCITED SEMI-INSULATING GaAs.** A new non-destructive method is presented for obtaining true resistivity ( $\rho$ ), mobility ( $\mu$ ), and electron concentration ( $n$ ) topography on photoexcited, semi-insulating GaAs. The method is based on the use of two perpendicular light slits, which join four removable in contacts on the periphery of the wafer to form a classical Greek-cross configuration. By placing contacts all around the periphery the whole wafer can be mapped. We give results for  $1.1 \mu\text{m}$  photoexcitation on a 3 in. low-pressure, liquid-encapsulated Czochralski wafer and compare with EL2 results on the same wafer. A by-product of the analysis is the determination of electron lifetime. Finally, the possibility of nondestructive dark electrical topography is discussed. (Author abstract) 22 refs.

**093901 FREQUENCY DEPENDENCE OF THE DIAGONAL CONDUCTIVITY OF A 2DEG IN GaAs HETEROSTRUCTURE IN THE QUANTUM HALL REGIME.** We have measured directly the diagonal conductivity of a 2DEG in GaAs/AlGaAs heterostructure via a capacitively coupled structure with dc bias at magnetic fields up to 6 tesla. From the ungated region of a sample of Corbino geometry, the diagonal conductivity at the Landau gap regions was measured via capacitive coupling to a non-quantized 2DEG in the source and drain capacitors. A strong frequency dependence was observed over a range of frequencies from 100 Hz to 20 kHz at the temperature of 1.3 K. The result is compared to the calculations from the percolation theory. From the measurements of two different temperatures, 1.3 and 4.2 K, the activation energy for the conductivity was estimated to be about 10% of Landau level spacing. (Author abstract) 10 refs.

**093902 ELECTRIC FIELD EFFECTS ON INTERSUBBAND TRANSITIONS IN QUANTUM WELL STRUCTURES.** We report on a Raman scattering study of the electric-field dependence of  $c_0 \rightarrow c_1$  intersubband transitions of photoexcited electrons in a 264 Å GaAs-Al<sub>0.3</sub>Ga<sub>0.7</sub>As quantum-well structure. The measured Stark shifts are in very good agreement with theoretical predictions. The intensity of the intersubband peak increases rapidly with applied field due to parity-mixing. In contrast to the enhanced broadening shown by exciton resonances, the width of  $c_0 \rightarrow c_1$  is nearly independent of the field. This feature is attributed to effects of structural disorder. (Author abstract) 23 refs.

**093904 ELECTRICAL PROPERTIES OF Ga/nGaAs(110) INTERFACES.** The electrical properties of moderately doped Ga/nGaAs(110) Schottky diodes, fabricated on both the clean cleaved and on the cleaved and air exposed GaAs(110) surface, have been studied. The current-voltage characteristic of both interfaces have an extremely large electron-hole recombination current. It is argued that this is produced by a disordered GaAs interfacial layer. Additionally, the capacitance-voltage characteristics of Ga/nGaAs(110) diodes, fabricated on the clean cleaved surface, are non-ideal and they preclude conventional analysis. The aging behavior of these interfaces has also been studied in detail. The electrical characteristics and the changes in the electrical characteristics with time are discussed in terms of the available microscopic theories of Schottky barrier formation. **093905 GROWTH OF HIGH PURITY GaAs AND Al<sub>x</sub>Ga<sub>1-x</sub>As FROM ADDUCT-PURIFIED METAL-ORGANICS.** By the use of direct injection inductively coupled plasma (ICP) emission spectroscopy we have identified silicon and zinc as volatile impurities in non-purified trimethylgallium (TMGa). The effect of these impurities on the electrical properties of GaAs layers is discussed. We have been able to remove these impurities to non-detectable levels using adduct purification techniques. The use of adduct-purified TMGa enabled us to grow GaAs layers with  $n_{77} K = 1.4 \times 10^{14} \text{ cm}^{-3}$  and  $\mu_{77} K = 137,000 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ . Low temperature photoluminescence (PL) data is presented for these high purity layers. Adduct purification also proved effective in greatly lowering silicon contamination in TMAI. Al<sub>x</sub>Ga<sub>1-x</sub>As and Al<sub>x</sub>Ga<sub>1-x</sub>As 2DEG structures grown with purified TMAI exhibited significantly improved electrical characteristics. (Author abstract) 17 refs.

**093906 TRANSIENT THERMOELECTRIC EFFECTS IN GaAs CRYSTALS.** Dynamic measurements of thermal diffusion processes of conduction carriers and phonons in GaAs crystals have been made in the temperature range 80-300 K using a pulsed laser-induced 'transient thermoelectric (TTE)' effect. The initial stage of the decay curves of TE voltages gives the carrier recombination times  $\tau_r$ , from which capture cross sections for electrons and holes are evaluated. During the second stage, three relaxation processes with relaxation times  $\tau_1$ ,  $\tau_m$ , and  $\tau_2$  were observed in both n- and pGaAs; the fast, intermediate, and slow components are associated with electrons at the  $\Gamma$ , X, and L point conduction bands for n-GaAs, and the light, split-off band, and heavy holes for p-GaAs, respectively. The final stage yields the thermal diffusion coefficient  $D_T$  and the thermal conductivity  $k$  for phonons in these crystals. (Author abstract) 16 refs.

**093907 METHOD OF MEASURING THE INHOMOGENEITIES OF THE ELECTROPHYSICAL PROPERTIES OF SEMIINSULATING GALLIUM ARSENIDE.** In connection with the extension of the domain of application of semiinsulating GaAs, a requirement to control the homogeneity of this material appeared in addition to the usual demands on its integral parameters. There are reports in the literature about the utilization of an optical method based on light absorption by deep centers and the method of resistance to spreading with bias lighting for this purpose. Because the distribution of deep centers does not determine uniquely the homogeneity of the electrophysical properties of semiinsulating GaAs, the possibilities of the second method of measuring the inhomogeneity was investigated in this paper. A description of the installation of this method and sufficiently contradictory data about the substance of the parameters being measured, the specific resistivity, and the photoconductivity signal, are contained in the literature. 8 refs.

**093908 ELECTRICAL CHARACTERIZATION OF A SUPERLATTICE.** Capacitance-voltage measurements have been performed on a periodic 20-20 Å GaAs-GaAlAs (30%Al), n-type ( $3 \times 10^{16} \text{ cm}^{-3}$ ) doped, 1.7  $\mu\text{m}$  thick structure. They show that the material is homogeneous in the growth direction. Deep traps produced by electron irradiation and detected by Deep Level Transient Spectroscopy, whose energy levels are well-known in bulk GaAs and GaAlAs, are found to emit electrons in a superlattice miniband, common to both materials, situated at 0.140 eV  $\pm$  0.02 eV above the conduction band edge of GaAs and at 0.130 eV below the conduction band edge of GaAlAs, providing a band offset of 0.27 eV. (Author abstract) 12 refs.

**093909 ELECTRICAL AND OPTICAL PROPERTIES OF HEAVILY DOPED Mg- AND Te-GaAs GROWN BY LIQUID-PHASE EPITAXY.** GaAs epitaxial layers doped with Mg and Te were grown on (100) GaAs substrates by liquid-phase epitaxy with a 6°C supersaturation temperature. Room-temperature carrier concentrations up to  $2 \times 10^{19} \text{ cm}^{-3}$  for p-type and  $2.6 \times 10^{19} \text{ cm}^{-3}$  for n-type dopants were obtained reproducibly. Carrier mobilities at 77 K in both n- and p-type layers showed a sharp drop at concentrations higher than  $2 \times 10^{19} \text{ cm}^{-3}$ . The full width at half maximum value and the relative intensity of the photoluminescent spectrum increased and decreased, respectively, with carrier concentration for both Mg- and Te-doped layers, and showed abrupt slope variations near a carrier concentration of  $1 \times 10^{19} \text{ cm}^{-3}$ . In Mg-doped GaAs layers, the peak wavelength of photoluminescence spectra increased with hole concentration due to band-gap shrinkage. On the other hand, the photoluminescence peak wavelength decreased with electron concentration due to a Burstein-Moss shift and to band-tailing effects in the Te-doped GaAs layers. (Author abstract) 14 refs.

**093910 COMPENSATION MECHANISM OF UNDOPE SEMI-INSULATING GaAs.** Carbon concentrations ( $C_{AS}$ ) of eight various undoped Si-GaAs samples are measured using the method of infrared local vibrational mode (LVM). It is found that all of the obtained ( $C_{AC}$ ) are less than  $5.20 \times 10^{14} \text{ cm}^{-3}$ . Net acceptor concentrations  $N_A - N_D$  could be deduced from the measured results of 1.1  $\mu\text{m}$  infrared absorption and Hall effect at 400K. It turns out that the  $N_A - N_D$  values of all samples are always larger than ( $C_{AS}$ ). There is an order of magnitude difference for those samples cut from the lower part of ingots. Therefore, the acceptors in those samples must arise from other impurities than carbon, in which boron ( $B_{AS}$ ) may be the main impurity. (Author abstract) 8 refs. In Chinese.

**093911 SOME PROPERTIES OF MIS STRUCTURES PREPARED BY PLASMA OXIDATION OF Al LAYERS ON GaAs.** Metal-oxide-semiconductor structures were fabricated on an n-type GaAs substrate at room temperature by plasma anodic oxidation of aluminum films evaporated on the GaAs substrate. Current and charge transient spectroscopies and low frequency C-U measurements were applied to the MOS capacitors. The optimum processing condition for the minimum interface-state-density is related to the properties of the Al film. Three apparent activation energies of the dominant DLTS peak ( $E_c - 0.5 \text{ eV}$ ,  $E_c - 0.67 \text{ eV}$ ,  $E_c - 0.72 \text{ eV}$ ) for three concentrations of donors ( $10^{24}$ ,  $2.7 \times 10^{23}$ , and  $1.4 \times 10^{22} \text{ m}^{-3}$ ) were determined. The differences in the values of the energies can be estimated as a consequence of the Poole-Frenkel effect with an extrapolated value of the true energy  $E_c - 0.75 \text{ eV}$ . From this point of view the observed DLTS peaks are attributed to the out migration of Ga atoms through the oxide layer and forming of a high resistivity O-compensated layer between the oxide and the semiconductor. (Edited author abstract). 21 refs.

**093912 ELECTRON CONDUCTION IN AN ATOMIC-LAYER-DOPED GaAs PLANE.** Electronic transport characteristics in Si atomic-layer-doped GaAs are investigated using Hall measurements. In the uni-

formly Si-doped GaAs crystals, the carrier concentration varies very little throughout the whole temperature range, while the atomic-layer-doped GaAs layer exhibits a strong temperature-dependent electron concentration with a minimum value around 100 K. The temperature dependence of the sheet resistance of the Si atomic-layer-doped GaAs is quite different from that of the uniformly Si-doped GaAs. The observed characteristics are interpreted by considering parallel conduction in the Si atomic-layer-doped GaAs. We propose a hypothetical model that the electrons are confined by a local potential well structure due to the random distribution of Si atoms in the atomic-layer-doped plane. Using this model, we also discuss the discrepancy reported so far between the doped layer thickness evaluated from magnetoresistance measurements and that from C-V profiling measurements. (Author abstract) 9 refs.

**093913 PHOTONIC SWITCHING BY TUNNELING-ASSISTED ABSORPTION MODULATION IN A GaAs SAWTOOTH STRUCTURE.** We report on an electrically controlled optical modulator using a novel GaAs sawtooth structure. This structure consists of alternating n-type and p-type delta-doped GaAs. Modulation of tunnelling-assisted absorption is achieved by changing the internal electric field which in turn is controlled by external bias. Modulation of light intensity is demonstrated over a broad spectral range of  $\Delta\lambda > 100$  nm. A contrast ratio of 1:1.7 of the opaque and transparent states is obtained. Low-voltage operation ( $\Delta V > 5$  V) and potential high-speed capability make the new device an attractive candidate for future photonic switching systems. (Author abstract) 5 refs.

**093914 STUDY OF THE CONDUCTION BAND NON-PARABOLICITY, ANISOTROPY AND SPIN SPLITTING IN GaAs AND InP.** The conduction bands in GaAs and InP have been studied very accurately through the cyclotron resonance over a wide range of energies using the photoconductive detection technique. Pronounced band non-parabolicity has been measured in GaAs and InP and the band anisotropy has been measured in GaAs. Values for the band-edge masses of  $0.660 m_0$  respectively have been determined. A five-level K-p model of the band structure in the presence of a magnetic field has been used to describe the data where resonant and non-resonant polaron contributions to electron energies are included in the theory. The non-parabolicity and spin-doublet splitting of the cyclotron resonance are well described by the employed formalism in both materials and the theory also gives a reasonable account of the anisotropy of the band in GaAs. The fit to experimental data allowed us to determine the matrix element of momentum Q between the higher conduction and valence bands in both materials. (Edited author abstract) 44 refs.

**093915 RESONANCE EFFECT IN INTER-SUB-BAND TRANSITIONS OF SINGLE QUANTUM WELLS.** Inter-sub-band transitions between electronic states of a single quantum well are considered. In such a double heterostructure a longitudinal polar optical mode emitted or absorbed in any transition can belong to one of a finite number of distinct branches. The transition rate is calculated here using fully quantum mechanical methods and its variation with the width of the well is explored. It is found that besides the familiar increase with

increasing width of the well, the rate exhibits periodic peaks. These constitute a resonance effect which arises whenever the conditions of incorporating a new polar branch are satisfied. Illustrations are given specifically for GaAs/Ga<sub>0.7</sub>Al<sub>0.3</sub>As single quantum wells. 13 refs.

**093916 OBSERVATION OF THE FERMI EDGE ANOMALY IN THE ABSORPTION AND LUMINESCENCE SPECTRA OF n-TYPE MODULATION-DOPED GaAs-AlGaAs QUANTUM WELLS.** A well defined sharp peak was observed in the absorption and luminescence spectra near the absorption edge of n-type modulation-doped GaAs-Al<sub>x</sub>Ga<sub>1-x</sub>As multiple quantum wells. The peak is assigned as the Fermi edge anomaly similar to the many-body effects in the soft x-ray spectra of metals. As the temperature was raised above 10 K, the peak disappeared, but it was restored by the application of magnetic field. The magnetic field dependence of the peak indicates that it has an excitonic character. (Author abstract) 20 refs.

**093917 ELECTROPHYSICAL PROPERTIES OF NONRECTIFYING CONTACTS TO n-GALLIUM ARSENIDE BASED ON Ni-Sn.** At present there are available a large number of studies on the relationship between thermal processing conditions and the electro-physical properties of nonrectifying contacts to GaAs based on eutectics of the noble metals with group IV elements. Study of the transition layer on an (Au-Ge)/Ni-n-GaAs nonrectifying contact reveals that the boundary between the contact material and the GaAs is inhomogeneous and consists of NiAs, NiGe, Ni<sub>3</sub>GeAs, and AuGeAs phases, in the compositions of which dopant elements may also appear. The processes of physicochemical interaction of transition metal alloys with gallium arsenide during formation of physicochemical interaction of transition metal alloys with gallium arsenide during formation of the nonrectifying contact are significantly less well studied. The goal of the present study is an experimental and theoretical investigation of nonrectifying contacts to n-GaAs, formed from Ni-Sn alloys. 13 refs.

**093919 MOMENTUM MIXING ENHANCEMENT OF BAND NON-PARABOLICITY IN GaAs-Ga<sub>1-x</sub>Al<sub>x</sub>As SUPERLATTICES.** We present pseudopotential calculations of the conduction and valence mini-band non-parabolicity in GaAs-Ga<sub>1-x</sub>Al<sub>x</sub>As superlattices of period approximately 80 Angstrom with various well widths. We find an order of magnitude difference between the non-parabolicity in structures with very narrow approximately 5 Angstrom and wider approximately 40 Angstrom wells. We relate this effect to the competition between quantum-size effects and zone-folding enhanced momentum mixing involving higher levels of X character. We show that the variation of the non-parabolicity of the electron energy with respect to its wavevector across the

small Brillouin zone takes on a complicated form which arises due to the anti-crossing behaviour of the higher conduction and lower valence mini-band states. Our results show that non-linear properties of semiconductor superlattices are a sensitive function of the form and position of the higher lying mini-bands which are normally ignored in simple models. (Author abstract) 5 refs.

**093920 ENERGY LOSS RATE OF ELECTRONS IN QUANTUM WELLS.** The Energy Loss Rate (ELR) of electrons in quantum wells, due to polar interaction with bulk longitudinal optical (LO) phonons is calculated, including the effect of dynamical screening of the electron-LO phonon interaction. The effect of a nonequilibrium distribution of LO phonons ('hot phonons') is included via a relaxation time approximation, keeping the relaxation time as a parameter. Numerical results are given for GaAs quantum wells, for the range of parameters (quantum well size, electron temperature, electron density) relevant to recent experimental determinations. The dynamical screening, which is a natural consequence of the energy-balance equations used, is shown to be relevant to the electron density dependence. (Edited author abstract) 14 refs.

**093921 QUANTUM LIMIT CYCLOTRON RESONANCE IN p-GaAs.** Electron scattering by neutral acceptors has been studied through far infrared ( $\lambda = 172 \mu\text{m}$ ) cyclotron resonance on p-GaAs at 4.2 K. It is found that (1) The inverse relaxation time is considerably smaller in the quantum limit than that predicted by dc transport theory in the absence of a magnetic field. (2) The same increases linearly with neutral acceptor concentration. (3) The electron momentum transfer cross section by neutral acceptor is by more than an order of magnitude smaller than that by neutral donor even in the quantum limit. (Author abstract) 17 refs.

**093923 STRUCTURED ULTRAFAST MOBILITY IN HIGHLY PHOTOEXCITED SEMICONDUCTORS.** We study the dependence of the mobility of the hot carriers of highly photoexcited plasmas in semiconductors on the irreversible evolution of their macroscopic state. We show that there are three different regimes of behavior of the ultrafast mobility transient: (i) structure (i.e. existence of maxima and minima) without overshoot at low fields, (ii) structure with overshoot at intermediate fields, (iii) normal evolution at intermediate to high fields. We name regimes (i) and (ii) hot carriers structured ultrafast mobility transients, and a criterion for their

occurrence is given. We present results of numerical calculations appropriate for electron transport in the central valley of GaAs. (Author abstract) 12 refs.

**093924 EFFECTS OF SHORT-RANGE AND LONG-RANGE ORDER ON THE ENERGY GAPS OF (GaAs)<sub>1-x</sub>Ge<sub>2x</sub> AND (GaSb)<sub>1-x</sub>Ge<sub>2x</sub>.** The effects of both short-range and long-range order on the energy gap of (GaX)<sub>1-x</sub>Ge<sub>2x</sub>, X = As or Sb, have been calculated by applying the Haydock recursion method to a variety of structural models for these materials. We find that realistic models for <100>-grown and <111>-grown alloys with different long-range order, but the same short-range order, have almost identical composition dependences of the energy gap. In contrast, hypothetical alloy structures with the same long-range order, but different short-range order, exhibit marked differences in energy gap. (Author abstract) 16 refs.

**093925 INDIRECT GAP RESONANT TUNNELING IN GaAs/AlAs.** A full band structure calculation of resonant tunnelling through AlAs barriers using a nearest neighbour tight binding method has been compared with experiment. We report good agreement of our calculation with measurements both qualitatively and quantitatively. The peak resonant current densities agree to within 20%, without the parameter adjustments used in other studies. The major contribution to the tunnelling current is found to result from X-like states in the AlAs barriers. This is the first rigorous theoretical confirmation of the conclusions arrived at from a number of other experimental studies. (Author abstract) 16 refs.

Cade, N.A. (GEC Research Ltd, Wembley Middlesex, Engl); Parmar, S.H.; Couch, N.R.; Kelly, M.J. *Solid State Commun* v 64 n 3 Oct 1987 p 283-286.

**093926 HIGH-FIELD ELECTRON TRANSPORT IN GaAs AND Ga(0.47)In(0.53)As RECTANGULAR QUANTUM WELLS.** Lattice-scattering limited velocity-field characteristics of GaAs and Ga(0.47)In(0.53)As quantum wells are computed by the Monte Carlo method. The velocity approaches a saturation value at 77 K for a field of about 0.2 kV/cm, while at 300 K it increases with the field as E<sup>0.5</sup>, with n around 0.8 to 0.9. Velocity run-away is produced for parabolic bands when the velocity is about (2 to 2.5) × 10<sup>7</sup> cm/s in GaAs and (3.3 to 3.8) × 10<sup>7</sup> cm/s in Ga(0.47)In(0.53)As. The run-away disappears when the effects of band non-parabolicity and inter-subband scattering are included. The velocity in GaInAs is larger by a factor of about 1.1 to 1.8. (Author abstract). 14 refs.

**093930 ENSEMBLE MONTE CARLO SIMULATIONS OF FEMTOSECOND ENERGY RELAXATION OF PHOTOEXCITED ELECTRONS IN BULK GaAs.** We present results of ensemble Monte Carlo simulations of the femtosecond relaxation of photoexcited electrons in bulk GaAs. Our results are in qualitative agreement with experimental data of Rosker, Wise and Tang (1986) and show that the fast relaxation component (approximately 34 fs) is primarily due to Γ → L scattering with a minor contribution from electron-electron scattering. The intermediate relaxation component (approximately 160 fs) is a result of the energy loss of electrons in the Γ valley which occurs chiefly by polar optical phonon (POP) scattering. (Author abstract) 11 refs.

**093931 USE OF LINEARLY GRADED COMPOSITION AlGaAs INJECTORS FOR INTERVALLEY TRANSFER IN GaAs: THEORY AND EXPERIMENT.** The use of semiconductor multilayers for hot electron injection and intervalley transfer have recently been demonstrated. In this study graded composition AlGaAs layers are used to generate a non-equilibrium distribution of electrons, in order to spatially control the transfer of electrons from the Γ to L valleys. The consequent growth of charge and field instabilities has been investigated both experimentally and by Monte-Carlo simulation. Emphasis has been placed on the exploitation of these hot electrons in transferred electron devices. Gunn diodes consisting of such graded gap layers, and transit regions of 1 μm have been fabricated by molecular beam epitaxy. They have been observed to oscillate at a frequency of GHz. Experimental results on these structures, together with their Monte-Carlo simulations, are discussed. (Edited author abstract)

## Etching

**093932 EFFECT OF DOPANTS CONCENTRATION ON RESOLUTION AND RATE OF LIGHT INDUCED ETCHING - PART II. APPLICATION TO n-GaAs.** This paper describes the model of light-induced etching (LIE, photoetching) including the space-charge region derived in Part I as applied to n-GaAs. Materials with high donor concentrations (from 10<sup>17</sup> to 10<sup>18</sup> cm<sup>-3</sup>) are shown to have the highest photoetching resolution. The model explains the decrease of etching rate with increased doping level in case of uniform illumination. Comparison with earlier published experiments on n-GaAs leads to a qualitative agreement. (Edited author abstract) 11 refs.

**093933 IN SITU ELECTRICAL AND OPTICAL MEASUREMENTS ON GaAs EPITAXIAL LAYERS DURING CHEMICAL ETCHING.** For the detailed characterization of epitaxial GaAs a chemical method has been devised. This method combines carrier concentration vs depth profile measurements with in-depth photocapacitance spectroscopy regarding the deep levels involved in a sample. This method was constructed on the following base: (1) Uniform chemical-etching by suitable etchants selected in the H<sub>2</sub>SO<sub>4</sub>-H<sub>2</sub>O<sub>2</sub>-H<sub>2</sub>O system and (2) In situ capacitance and photocapacitance measurements on the etchant as well as the other electrolyte Schottky contact. In applying the method there is almost no restriction on the magnitude of both the carrier concentration and the sample-thickness. It can, therefore, be applied to various samples, including their interface regions. Here, details of the method and typical results are presented. (Author abstract) 30 refs.

**093934 STUDY OF GaAs ETCHING IN ALKALINE H<sub>2</sub>O<sub>2</sub> SOLUTIONS.** We studied the etching kinetics of GaAs in alkaline H<sub>2</sub>O<sub>2</sub> solutions. The influence of the solution composition and of complexing agents on etching and oxide formation was investigated. Current-potential measurements with a micro-electrochemical flow cell allowed us to distinguish between chemical and electrochemical etching modes. From these results, suggestions are made concerning the dissolution mechanism. The results are compared with those found for acidic H<sub>2</sub>O<sub>2</sub> systems. 24 refs.

**093935 CORRELATION OF THE ETCHING MORPHOLOGY WITH THE MAIN MIDGAP DONOR DISTRIBUTION IN UNDOPED, SEMI-INSULATING GaAs.** The authors report on the use of a modified AB etch to delineate electrically inhomogeneous regions in undoped material. The features exposed by this etch have been correlated with the spatial distribution of the main deep donor (normally known as EL2) in Si GaAs. Based on the results presented, we conclude that the etch rate of an AB etch with reduced HF content is extremely sensitive to the local electronic properties of the substrate. The etch rate is, in fact, so dependent on the local EL2 content that this etchant actually produces an 'etch map' of the EL2 distribution in Si GaAs wafers. Our results are fully consistent with the recent correlation between the etch rate of standard AB etchant and the position of the Fermi level. 13 refs.

**093936 TEMPERATURE DEPENDENCE OF THE ETCH RATES OF GaAs, AlGaAs, InP, AND MASKING MATERIALS IN A BORON TRICHLORIDE-CHLORINE PLASMA.** The pressure, temperature, and power effects are examined independently of each other for GaAs, AlGaAs, and InP in a boron trichloride:chlorine plasma. Conditions are examined for which chemical etching and for which sputter-assisted etching occur. The variations of etch rate with change in temperature are discussed. For fixed temperatures the GaAs etch rates actually decrease with increased power in the low pressure regime. For InP the etch rates increase with increasing power at fixed temperatures. (Author abstract) 27 refs.

**093937 248 nm LASER ETCHING OF GaAs IN CHLORINE AND OZONE GAS ENVIRONMENTS.** KrF laser etching of GaAs in  $\text{Cl}_2$  and  $\text{O}_3$  gas ambients by direct laser illumination is reported. The etch depth per pulse in  $\text{Cl}_2$  was found to be linear versus the laser fluence on the sample in the 0.2-1.1 J/cm<sup>2</sup> range. It increased as a function of the  $\text{Cl}_2$  pressure up to 6 Torr and slightly decreased for pressures above this value. It also decreased as a function of the laser repetition rate. Very smoothly etched surfaces were obtained after irradiation using the  $\text{Cl}_2$  and  $\text{O}_3$  etching gases. Auger analysis of the etched GaAs surfaces shows almost no traces of chlorine after etching in  $\text{Cl}_2$ , whereas a thick oxide layer of about 1500 Å thickness was found after etching in ozone. (Author abstract) 13 refs.

**093938 IMPERFECTIONS OF GAS-PHASE EPITAXIAL GaAs, AS REVEALED IN SYRTLE'S ETCHANT.** The imperfections revealed in Syrtle's etchant in the form of dome-shaped etching figures are clusters of impurity defects in thin layers of the epitaxial film. These inhomogeneities may form as a result of gettering of impurity atoms at sinks and thus reduce the concentration of inactive contaminating impurity. It is shown that the observed imperfections are electrically active and create regions of nonradiative recombination. 4 refs. In Russian.

**093940 STUDY ON ETCHING PARAMETERS OF A REACTIVE ION BEAM ETCH FOR GaAs AND InP.** Some etching characteristics for GaAs and InP with  $\text{Cl}_2$  gas using a reactive ion beam etching (RIE) system have been studied. The employed etching gas was ionized by electron cyclotron resonance (ECR) at a gas pressure of about  $6 \times 10^{-4}$  Torr; the applied microwave power was 300 W. The etch rate was measured as a function of the substrate temperature and the applied ion extraction voltage. At low temperatures, the etch rate of InP was proportional to the five halves of the extraction voltage. This agreed well with a theoretical consideration. The maximum etch rates for InP and GaAs were 2.0 and 1.2 µm/min, respectively, both at 200°C. (Author abstract) 15 refs.

**093943 NANOMETER STRUCTURE FABRICATED BY FIB AND ITS OBSERVATION BY STM.** Fabrication of a fine ridge pattern on single quantum well layer of GaAs/AlGaAs system is carried out by means of enhanced etching induced by bombardment of a 50-keV focused Ga-ion beam. A 50-nm wide ridge pattern can be stably obtained, though the etched profile shows a tapered or overhanged side wall depending on scanning direction in sample surface plane. A scanning tunneling microscope is utilized for evaluation of three-dimensional feature of micro-fabricated Si. It is demonstrated that a grid pattern with a periodicity of 160 nm and a groove depth of 30-50 nm can be visualized with a resolution less than 10 nm in lateral direction and less than 5 nm in depth. (Author abstract) 7 refs.

## Fracture

**093946 FRACTURE TOUGHNESS OF PURE AND In-DOPED GaAs.** The use of GaAs for microelectronic devices is impeded by the occurrence of detrimental extended crystal defects, which appear during growth or subsequent processing. The ability of a material to resist crack extension from preexisting flaws which can be generated at several steps of device processing is conveniently expressed by  $K_{IC}$ , the critical stress intensity factor for mode I fracture. The authors report on preliminary results obtained with the accurate technique of pre-cracked profiled DCB samples. This technique is particularly well suited to crack tip plasticity and brittle-ductile transition studies. In this note, room temperature - i.e., in the fully brittle range - experiments are

reported. 19 Refs.

## Growing

**093947 LOW PRESSURE OMVPE GROWTH OF GaAs USING A SOLID ELEMENTAL ARSENIC SOURCE AND TEG.** A new low pressure process for the growth of GaAs using triethylgallium (TEG) and a solid elemental arsenic source has been demonstrated. GaAs epitaxial layers with specular surface morphology have been obtained. N-type background free carrier concentrations on the order of  $5 \times 10^{16} \text{ cm}^{-3}$  with room temperature mobilities around 4500 cm<sup>2</sup>/V/s are measured in these samples. The ability to grow GaAs epi layers with good surface morphology using a solid elemental arsenic source makes it more acceptable as a relatively safe industrial production process. **093949 MATHEMATICAL MODELLING OF THE LIQUID ENCAPSULATED CZOCHRALSKI GROWTH OF GALLIUM ARSENIDE: I. HEAT FLOW MODEL.** The temperature distribution in a GaAs crystal during growth has been determined using a finite element model of the heat flow in a LEC Czochralski system. The model results which include estimated values for the boundary parameters, are shown to be in good agreement with analytical solutions to the heat flow equations, using simplified boundary conditions, and to experimental temperature measurements in a LEC Melbourn grower at 3.04 MPa pressure. (Author abstract) 21 refs.

Schvezov, C. (Univ of British Columbia, Vancouver, BC, Can); Samarasekera, I.V.; Weinberg, F. *J Cryst Growth* v 84 n 2 Aug 1987 p 212-218.

**093950 MATHEMATICAL MODELLING OF THE LIQUID ENCAPSULATED CZOCHRALSKI GROWTH OF GALLIUM ARSENIDE: II. STRESS MODEL.** The stress distribution in GaAs crystals, during growth, has been calculated with finite element numerical methods, assuming thermoelastic crystal behavior. These results are compared to analytical solutions and found to be in good agreement with axisymmetric solutions, and to a lesser extent with plane strain solutions. Based on calculated thermal stresses in the crystal, the Von Mises stresses have been determined throughout the crystal. The local effective resolved shear stress leading to dislocation generation and movement was determined by subtracting reported values of yield stress and critical resolved shear

stress from the maximum resolved shear stress. The results show high dislocation densities occur in the central region and near the outside surface of the crystal in agreement with reported observations of etch pit density distributions in GaAs. (Author abstract) 15 refs.

**093951 EFFECTS OF CRUCIBLE MATERIAL ON UNDOPE LEC GaAs CRYSTALS.** We have grown undoped GaAs crystals using the LEC technique with crucibles made of new materials, namely a sintered AlN crucible, a sintered  $\text{Si}_3\text{N}_4$  crucible and a  $\text{Si}_3\text{N}_4$  coated quartz crucible, and have examined the properties of crystals grown from these crucibles. It is possible to grow single crystals in each crucible, but larger amounts of arsenic are lost from the melt by vaporization with the AlN and  $\text{Si}_3\text{N}_4$  crucibles during growth. Silicon on the order of  $10^{15}$ - $10^{16}$  atoms/cm<sup>3</sup> is detected in the crystals grown from the  $\text{Si}_3\text{N}_4$  and  $\text{Si}_3\text{N}_4$  coated quartz crucibles, and the conductivity of the crystals becomes n-type. On the other hand, for the AlN crucible, a high concentration of aluminum and carbon of the order of  $10^{17}$  atoms/cm<sup>3</sup> is detected and the crystals show p-type conductivity. The incorporation of a great deal of aluminum seems to be the main reason for the high carbon concentration. (Author abstract) 8 refs.

**093953 MAGNETIC FIELD EFFECT ON RESIDUAL IMPURITY CONCENTRATIONS FOR LEC GaAs CRYSTAL GROWTH.** A horizontal magnetic field applied LEC (MLEC) apparatus, for mass-producing large diameter undoped LEC GaAs, has been newly developed. The detailed magnetic field effect on residual impurity concentrations has been studied. The carbon and boron concentrations have been found to be decreased by the MLEC technique, related to the applied magnetic field strength. The thermochemical mechanism for impurity incorporation into GaAs single crystals has been clarified through this study. The oxidation rate of free gallium and deoxidation rate of carbon oxide are shown to be the rate limiting reactions determining the impurity incorporation rate into GaAs crystals. The obtained results suggest that applying a magnetic field to molten GaAs suppresses the chemical reaction closely related to the impurity incorporation into resultant GaAs single crystals. The experimental results show good agreement with this predicted thermochemical mechanism. (Edited author abstract) 6 refs.

**093954 EFFECT OF CRYSTAL ORIENTATION ON DISLOCATION FORMATION IN LEC GaAs.** The etch pit density (EPD) in  $\langle 111 \rangle$  and  $\langle 100 \rangle$  semi-slices of a twinned LEC crystal was measured and compared to the thermal stress patterns theoretically calculated. It is seen that there is a qualitative agreement between stress and dislocation distribution in the two

differently oriented portions of the slices. Evidence is given that  $\langle 100 \rangle$  oriented crystals are more sensitive to thermal stress and are more difficult to grow without dislocations indeed. The discrepancies in quantitative EPD and total stress distributions have been ascribed both to the approximation in the theory of stress model and to the presence of point defects which obviously play as dislocation source. (Author abstract) 12 refs.

**093957 MOLECULAR-BEAM-EPITAXIAL GROWTH OF GaAs ON HIGH-TEMPERATURE HYDROGEN-ANNEALED (100) SILICON.** Superior-quality GaAs epitaxial layers have been grown by molecular beam epitaxy on high-temperature hydrogen-ambient annealed silicon (100) substrates. Rutherford backscattering and channelling of 2.1 MeV He<sup>+</sup> ions and transmission electron microscopy techniques have been used to characterize these layers. Comparative studies indicate that the epitaxial layers grown on hydrogen-ambient annealed substrates have a superior surface morphology and a lower interface disorder than those on chemically cleaned (100) substrates. Cross-sectional transmission electron micrographs show the presence of a high density of threading dislocations, stacking faults and twins in the GaAs layers grown on the chemically cleaned silicon (100) substrates. In contrast, a significant reduction in the density of these defects is observed in the layer grown on the preannealed substrates. (Author abstract) 16 refs.

**093961 ANALYSIS OF THE CRYSTAL WEIGHING METHOD APPLIED TO LIQUID ENCAPSULATED CZOCHRALSKI GROWTH.** We analyze theoretically the force detected by a crystal weight sensor during liquid encapsulated Czochralski (LEC) growth. Based on a realistic model for LEC pulling, an expression for the differential weight gain signal (DWGS) is derived in terms of fundamental dynamic variables. The treatment gives an exact account of the mass growth, and the effects of buoyancy and melt meniscus dynamics. The generally complex relationship is well approximated by a simple modification of the results found recently for the regular Czochralski (CZ) case. The case of GaAs growth with B<sub>2</sub>O<sub>3</sub> encapsulation provides material constants in the quantitative discussion. (Edited author abstract) 28 refs.

**093962 EFFECTS OF CERTAIN GROWTH PARAMETERS ON HOLE AND ELECTRON TRAPS IN LPE GaAs.** The purpose of the present paper is to investigate the behavior of hole traps A and B in liquid phase epitaxial (LPE) layers of GaAs materials. The effects of growth rates and the epitaxial temperatures are reported. It is noted that hole traps A and B will be present in equal amounts only when a suitable growth rate is adopted. After which, the greater the growth rate, the greater the divergence between the concentrations of A and B. The probable mechanism of this phenomenon has been discussed on the basis of our thermochemical model. 10 refs.

**093963 MICROSCALE PHENOMENA IN BULK GaAs CRYSTALS: THE EFFECT OF THERMAL GRADIENTS.** Undoped bulk crystals of gallium arsenide were grown in a unique Bridgman apparatus. The effect of the temperature gradient impressed over the melt, in conjunction with the role of the melt composition (arsenic source temperature), was investigated. Crystals were photo-etched to produce the interface striation patterns and the defect structures characteristics of the growth conditions. At low gradients the interface was found to be sharply curved, but uniform electron-beam induced current and cathodoluminescence intensities were observed. As the temperature gradient over the melt was increased the interface became flatter, and the uniformity of the EBIC and CL signals deteriorated. Growth of crystals from nonstoichiometric melts resulted in increased dislocation densities, with EBIC and CL yields unique to the

Ga:As ratio in the melt. Deep level populations were also observed to respond to variations in the melt composition. (Author abstract) 12 refs.

**093964 LIQUID PHASE EPITAXY GROWTH OF GaAs/GaAlAs MULTI-QUANTUM WELL STRUCTURES.** Experiments in liquid phase epitaxial fabrication of thin GaAs/GaAlAs layers over a planar substrate have been carried out. Layer thicknesses smaller than 300 Å were routinely obtained, with the best result being 120 Å. Interface sharpness between the layers is approximately 10 Å, which is comparable to OMCVD results, but the layers' thicknesses are usually not uniform. Of the experimental parameters, the growth time and the cooling rate seem to have the largest effect on the obtained layer thickness, while the growth temperature and the substrate crystallographic orientation produce less noticeable effects. Quantum effects in the growth layers were observed by photoluminescence measurements. (Author abstract) 15 refs.

**093968 SILICON MIGRATION DURING MBE GROWTH OF DOPED (Al,Ga)As FILMS.** It is well established that in MBE-grown GaAs/(Al,Ga)As selectively doped heterojunctions the electron mobility in the two-dimensional electron gas (2-DEG) is considerably lower for a GaAs grown on (Al,Ga)As (inverted) interface than for (Al,Ga)As grown on GaAs (the so-called normal structure). It has been suggested that there are two principal processes responsible for the observed difference between normal and inverted struc-

tures. One is crystallographic, and requires that the interface perfection, or more probably the smoothness, is lower than GaAs is grown on (Al,Ga)As. The second is that Si donors migrate from the doped (Al,Ga)As into the undoped GaAs in the inverted but not the normal structure. It is important to understand the migration behavior, both in the context of present devices such as HEMTs and also for the design of future devices which may be based on very thin layers of highly doped material (e.g., hot electron devices or heterojunction bipolar transistors). This understanding is the motivation for the present work, in which we present results relating to two main problems: (i) the possible concentration dependence of Si migration and (ii) the mechanism of this migration. 18 refs.

**093969 CHARACTERIZATION OF SURFACE FACETING ON (110)GaAs/GaAs GROWN BY MOLECULAR BEAM EPITAXY.** Commonly observed faceting of (110) GaAs grown by molecular beam epitaxy has been systematically investigated. Faceted (110) films were examined with microscopic, electrical, and optical techniques. The geometry of the facets with respect to the GaAs crystal was determined and an atomic model of facet formation was derived from experimental results. The study ultimately led to the elimination of facet formation on (110) GaAs grown by molecular beam epitaxy. (Author abstract) 12 refs.

**093970 NOVEL ELECTRON-BEAM EXPOSURE EPITAXY FOR GROWING GaAs FILMS ON FLUORIDE/SI STRUCTURES.** A novel heteroepitaxial technique, which we call electron-beam exposure epitaxy (EBE-epitaxy), has been employed in growing GaAs films on  $\text{CaF}_2/\text{Si}(111)$  structures. In this method, prior to the growth of GaAs films, the surfaces of  $\text{CaF}_2$  are exposed to an electron-beam under impingement by arsenic fluxes. It has been found that thin GaAs films with excellent crystallinity and smooth surfaces can be obtained on the  $\text{CaF}_2/\text{Si}(111)$  structures. It has also been found that mixing of regular (type A) and rotationally twinned (type B) crystallites does not occur in the films, but that they show preferential and dominant type A orientation which is identical to that of the  $\text{CaF}_2$ . (Author abstract) 8 refs.

**093971 MOLECULAR BEAM EPITAXIAL GROWTH OF GaAs ON SILICON WITH BURIED IMPLANTED OXIDES.** We report results of direct growth of GaAs by molecular beam epitaxy on nominally (100) oriented silicon with buried implanted oxides. Rutherford backscattering and transmission electron microscopy techniques have been used to characterize these layers. The formation of hillocks and a uniform layer of GaAs in the intervening regions between hillocks have been observed. Microtwins, dislocations and antiphase domain boundaries are the predominant defects observed in these layers. (Edited author abstract) 13 refs.

**093972 SUBSTRATE ORIENTATION AND PROCESSING EFFECTS ON GaAs/SI MISORIENTATION IN GaAs-ON-SI GROWN BY MBE.** The angular misorientation of GaAs epitaxial layers grown on silicon substrates by molecular beam epitaxy has been measured using X-ray diffraction. A significant misorientation, or tilt, between the epitaxial layer and the substrate has been observed. The magnitude of the tilt depends on the initial

substrate orientation, the silicon substrate type (float zone or Czochralski), postgrowth annealing, and epitaxial layer thickness. In almost all cases, the sense of the tilt is such that the GaAs  $\langle 001 \rangle$  lies between the surface normal and the silicon  $\langle 001 \rangle$ . While the presence of interfacial dislocations with Burgers vectors that are approximately parallel to the heterointerface does predict a tilt between the substrate and the epitaxial layer, the sense of the tilt that arises from these dislocations is opposite to that observed experimentally. A model, based on the relief of misfit by dislocations inclined approximately 45 degrees to the interface, is proposed that correctly describes the observed tilt. (Author abstract) 19 refs.

**093974 SOURCE OF CARBON CONTAMINATION IN GaAs GROWN BY METAL-ORGANIC-CHLORIDE ( $\text{Ga}(\text{CH}_3)_3/\text{AsCl}_3/\text{H}_2$ ) VPE.** Comparative characterization of two types of GaAs was conducted using photoluminescence (PL) and Hall measurements. The first is of GaAs grown by metal organic (MO)-chloride VPE, in which system the trimethylgallium ( $\text{TMG}$ ;  $\text{Ga}(\text{CH}_3)_3$ ) vapor is substituted as the Ga metal source in the chloride ( $\text{Ga}/\text{AsCl}_3/\text{H}_2$ ) VPE system. The second type is of GaAs grown either by  $\text{CH}_4$  or by  $\text{C}_2\text{H}_6$  doped chloride VPE. MO-chloride VPE GaAs was contaminated with carbon. The possible carbon source is considered to be ethane since the  $\text{C}_2\text{H}_6$ -doped chloride VPE system produced GaAs electrically close to GaAs grown in the MO-chloride VPE system. This is demonstrated by the fact that mass spectrometric analysis of hydrocarbons produced by thermal decomposition of TMG revealed ethane along with methane. (Author abstract) 24 refs.

**093975 STRUCTURAL FEATURES OF MBE GROWN VERY SHORT PERIOD GaAs-AlAs SUPERLATTICES.** Very short period GaAs-AlAs superlattices (period less than 25 Å) were grown by molecular beam epitaxy. Three techniques were carried out to study these samples: transmission electron microscopy, X-ray diffraction, and photoluminescence. Diffraction techniques have proved to be particularly suitable for the analysis of this type of samples. By combining electron and X-ray diffraction, the origin of the fine structure of diffraction peaks could be explained with respect to the growth process. Owing to the high sensitivity of diffraction techniques, very small period variations (less than one monolayer) could be evidenced. The period of the three described samples was shown to be a fractional number of monolayers, which is related to the growth conditions used in this MBE set-up. Photoluminescence results give evidence of the high quality of the superlattices, and are fully consistent with those given by the diffraction techniques. (Author abstract) 19 refs.

**093976 MIGRATION-ENHANCED EPITAXY OF GaAs AND AlGaAs.** Surface migration is effectively enhanced by evaporating Ga or Al atoms onto a clean GaAs surface under an As-free or low As pressure atmosphere. This characteristic was utilized by alternately supplying Ga and/or Al and As to the substrate surface for growing atomically-flat GaAs-AlGaAs heterointerfaces, and also for growing high-quality GaAs and AlGaAs layers at very low substrate temperatures. The migration characteristics of surface adatoms have been investigated through reflection high-energy electron diffraction measurements. It was found that different growth mechanisms are operative in this method at both high and low temperatures. Both these mechanisms are expected to yield flat heterojunction interfaces. By applying this method, GaAs layers and GaAs-AlGaAs single quantum-well structures with excellent photoluminescence were grown at substrate temperatures of 200 and 300°C, respectively. (Author abstract) 28 refs.

**093977 PRECIPITATE IDENTIFICATION IN V- AND Cr-DOPED LEC GROWN GaAs.** Precipitates which form during the LEC growth of vanadium- and chromium-doped GaAs are shown to be predominantly the respective transition metal arsenides VAs and CrAs. In general, the precipitation follows closely upon the transition from single crystal to polycrystalline growth which arises primarily from factors such as constitutional supercooling and twinning. As a result, the precipitates are usually found at grain boundaries in the non-single crystal regions near the termination of growth. A scanning electron micrograph of a polished crystal section, typical of those cut from the base of V-doped crystals, is shown. (Edited author abstract) 6 refs.

**093978 ORIENTED OVERGROWTHS IN MOVPE-GROWN GaAs.** The crystallographic structure of crater-containing oriented overgrowths on GaAs epitaxial layers grown by metalorganic vapor phase epitaxy (MOVPE) has been studied by transmission electron microscopy and diffraction. The craters are the visible outward sign of polycrystalline constructions of 6 grains or more having low order twin relations with the matrix. Anisotropic development of the facets of the grains is proposed to be the growth mechanism of the hillock. Stacking fault pyramids are present but their correlation with craters and overgrowths is not systematic. (Author abstract) 57 refs.

**093979 GROWTH CELLS OF HEAVILY In-DOPED LEC GaAs CRYSTALS.** We observed the generation of growth cells in heavily In-doped LEC GaAs crystals (with an In concentration of  $1 \times 10^{21}$  atoms/cm<sup>3</sup> in the initial melt) grown under various growth conditions, and examined the generation of growth cells with respect to the growth parameters. Growth cells are generated at the top of the convex solid-liquid interface, and the angle over which the growth cells spread changes with the curvature of the solid-liquid interface. The fraction solidified at which growth cells first appears ( $g_{cell}$ ) depends on the pulling speed and the axial temperature gradient. For instance, when the axial temperature gradient is kept constant at 80°C/cm, the values of  $g_{cell}$  are around 0.22, 0.45 and 0.70 for the pulling speeds of 9, 5 and 3 mm/h, respectively. When the pulling speed is kept constant at 5 mm/h, the values of  $g_{cell}$  are 0.45 and 0.13, for axial temperature gradients of 80 to 20°C/cm. (Author abstract) 9 refs.

*Cryst Growth* v 87 n 4 Mar 1988 p 547-553.

**093980 GROWTH OF GaAs PLATE CRYSTAL BY THE LIQUID ENCAPSULATED STEPANOV METHOD.** We have successfully grown two sizes of GaAs plate crystals: one with a width of 36 mm, a thickness of 10 mm and a length of 100 mm, and the other with a width of 36 mm, a thickness of 4 mm and a length of 90 mm. First, the wettability of die materials, such as PBN, quartz, graphite, hBN, AlN and sapphire, with respect to the GaAs melt were examined and it was found that these materials are not wet. Then, the plate crystals were grown by LES method using the graphite growth die. The head of the grown GaAs plate was a single crystal, but the surface became polycrystalline after shape-controlling by the die. There seems to be the relationship between the generation of the polycrystals and the change in the shape of the solid-liquid interface. (Author abstract) 9 refs.

**093982 INITIAL GROWTH CONDITIONS OF GaAs ON (100) Si GROWN BY MIGRATION-ENHANCED EPITAXY.** This paper investigates the effect of initial growth conditions on the structural and optical properties of GaAs and (AlGa)As/GaAs quantum well heterostructures (QWH) on (100) Si. Samples are grown by migration-enhanced epitaxy (MEE) at 300°C. Only the growth conditions of the first GaAs monolayer on Si substrates are varied. Optimization requires: 1) no exposure of the hot Si surface to As, and 2) Ga-dominated initial growth conditions. Sharp low-temperature excitonic luminescence (8.0 meV (FWHM) for  $L_z = 2$  nm) confirms the smooth heterointerfaces of the MEE-grown layers. Samples grown by conventional MBE at 300°C show a clearly poorer crystal quality. (Author abstract) 13 refs.

**093983 ELECTRON-MICROSCOPE STUDIES OF THE SURFACE OF EPITAXIAL GaAs LAYERS IN THE PROXIMITY OF THE (111)A FACE.** Electron-microscope studies have been carried out on the relief of the growth surface of epitaxial gallium arsenide layers in the vicinity of the (111)A face. The quantitative characteristics of the elements of the relief have been determined: the density of growth centers on a singular face, the height of the steps, and the distances between steps in the vicinal planes. The parameters of the growth steps are shown to depend on the orientation of the face and the concentration of the growth components in the vapor phase. (Author abstract) 7 refs.

**093984 GROWTH OF GaAs MILLIMETER WAVE IMPATT DIODE MATERIAL USING LOW TEMPERATURE VAPOR PHASE EPITAXY.** Chloride transport vapor phase epitaxy has been one of the most widely used techniques for the epitaxial growth of GaAs

for microwave device applications. Unfortunately, this technique has been limited to the growth of relatively low frequency (<40 GHz) structures due to its inherently high growth rate at typical deposition temperatures (approx. 750°C). It is well known, however, that the growth rate is a strong function of deposition temperature and that growth in the kinetically limited low temperature regime not only allows one to achieve low growth rates but also improves both thickness and doping uniformity. It would therefore seem that low temperature chloride transport vapor phase epitaxy (LTVPE) would be well suited for the growth of GaAs device structures for mm-wave applications. We report here the use of LTVPE for the routine production of double drift Read profile IMPATT diode structures for operation at 44, 60, and 94 GHz. State-of-the-art power and efficiency results are obtained from diodes produced with this material and excellent uniformity is observed across 2 inch diameter wafers. (Author abstract) 26 refs.

**093985 AXIAL CHANNELING STUDIES OF HETEROEPITAXIAL In<sub>0.25</sub>Ga<sub>0.75</sub>As ON GaAs.** Axial channeling results are presented for the analysis of the heteroepitaxial growth structure of In<sub>0.25</sub>Ga<sub>0.75</sub>As on <100> GaAs by MBE. The strain measurements have utilized inclined-direction axial dechanneling and angular scans. Anomalously large dechanneling along the declined <110> axis relative to the <100> growth direction indicates the presence of lattice strain due to lattice mismatch. Imperfections or lattice defects in dislocation nature in the epitaxial layer also give rise to significant dechanneling. (Author abstract) 8 refs.

Yin, Shiduan (Chinese Acad of Sciences, Beijing, China); Wu, Chunwu; Zhang, Jingping; Liu, Jiarui; Zhu, Peiran; Wang, Yu. *Solid State Commun* v 65 n 10 Mar 1988 p 1181-1183.

**093986 DEVELOPMENT OF HIGHLY UNIFORM GaAs EPITAXIAL WAFERS WITH A THREE-INCH DIAMETER.** With the demand for high frequency and high output GaAs FETs for use in transmitters and receivers in satellite communications and microwave circuits, chip sizes are becoming large. In the manufacturing processes for FETs, to decrease the number of processes and improve the yield, it is desirable to increase the diameter and improve the uniformity of GaAs epitaxial wafers. The two-inch GaAs VPE (Vapor Phase Epitaxial growth) wafer has been produced as a material for FETs, and to meet the above-mentioned requirements three-inch VPE wafers have been developed. To make the reactor large enough for the development of the three-inch wafer, the vapor phase growth techniques accumulated over the last few years were put to use, and simulation software which analyzes gas flow and thermal flow in the reactor tube to optimize the growth conditions in the newly-designed, larger reactor tube was developed. 2 refs.

**093987 ULTRA-HIGH THROUGHPUT OF GaAs AND (AlGa)As LAYERS GROWN BY MOLECULAR BEAM EPITAXY (MBE) WITH A SPECIALLY DESIGNED MBE SYSTEM.** The ultra-high throughput of extremely uniform GaAs and (AlGa)As layers with excellent surface morphology can be realized by MBE with a new MBE system designed for both a drastic increase of the throughput and a reduction of the surface defect density. The simultaneous growth of seven 5-cm-dia. epilayers can be achieved with a thickness variation of less than 2% by optimizing the effusion cell geometry. A computer-controlled growth sequencer and a newly developed source recharging system are incorporated for automatic growth, and operated continuously day and night without venting the growth chamber even

during source recharging. The surface defect density has been reduced to less than  $50/\text{cm}^2$  by the introduction of a modified Ga cell and a face-down sample-transfer system. This system allows the growth of nearly 100 GaAs FET or HEMT wafers each day (24 hr). The devices constructed from these wafers showed excellent performance. (Author abstract) 15 refs.

**093988 MINIMISATION OF THERMAL STRESSES DURING THE GROWTH OF GaAs CRYSTALS.** Undesirably high dislocation densities in Czochralski growth gallium arsenide crystals are generally accepted to be due to high thermal stresses generated by temperature gradients in the crystal during growth. Detailed numerical calculations are presented, using finite element methods, for partially and fully grown crystal geometries to calculate the resulting stresses. By varying such parameters as the ambient temperature, heat transfer coefficient and crystal geometry the dislocation density can be minimized and hence optimum growth conditions predicted. It is shown that the optimum conditions during the initial stages of crystal growth are radically different to those required for the mature crystal geometry. (Author abstract) 16 refs.

**093990 GROWTH OF GaAs ON PREFERENTIALLY ETCHED GaAs SURFACES BY MIGRATION-ENHANCED EPITAXY.** The migration mechanism of surface adatoms during migration-enhanced epitaxy is quite different from that expected in conventional molecular beam epitaxy. This difference is clearly demonstrated in the cross-sectional views of GaAs layers grown on preferentially etched, undercut-mesa stripes. Definite crystal facets of (110) appear in the layers grown by migration-enhanced epitaxy, in contrast to the (111)B facets in the layers grown by molecular beam epitaxy. The migration mechanisms of these two growth methods are discussed in order to interpret the differences in the faceting characteristics. (Author abstract) 13 refs.

**093991 APPLICATION OF RHEED INTENSITY EFFECTS TO INTERRUPTED GROWTH AND INTERFACE FORMATION DURING MBE GROWTH OF GaAs/(Al, Ga)As STRUCTURES.** There is a diffraction-induced phase effect in the RHEED intensity oscillation technique used in MBE, whereby intensity maxima only correspond to monolayer completion for very restricted conditions. In particular, the angle of incidence of the primary beam is extremely critical. The effect occurs because the total intensity at the measured position of the specular beam is always derived from at least two different diffraction processes, which do not have the same phase relation to monolayer formation. It can be accommodated either by a systematic series of measurements to establish an empirical relationship between incidence angle and phase, or by Fourier transform techniques. Unless full account is taken of this purely diffraction-induced effect, very misleading results can be obtained for the time

constants of the recovery period following cessation of growth and this is illustrated for GaAs. The effect also has important implications for the growth-interrupt technique. In addition, it is shown that for heterojunction formation in the GaAs/(Al,Ga)As system, adatom (Ga and Al) migration lengths are of greater importance than the position in the monolayer at which the composition is changed, and that RHEED can provide only limited information on the interface structure. (Author abstract) 20 refs.

**093992 LOW-FREQUENCY NOISE IN GaAs LAYERS GROWN BY MOLECULAR BEAM EPITAXY.** Low-frequency noise in n-GaAs layers grown by molecular beam epitaxy has been studied for various carrier concentrations and device dimensions. The noise decreases linearly with an increase in total carriers and layer thickness. The frequency dependence of the noise varies at a rate of  $f^{-1.5}$  in the devices with SnAu contacts, and at the rates of  $f^{-1.2}$  to  $f^{-2.0}$  in those with AuGe contacts. SnAu ohmic contacts have noise levels 20 db lower than those of AuGe contacts. Surface cap layers either doped to n- or p-type have little effect on the overall frequency dependence of the noise. (Edited author abstract) 14 refs.

**093993 DISLOCATION REACTIONS AND LINEAGE FORMATION IN LIQUID ENCAPSULATED CZOCHRALSKI GROWN GaAs CRYSTALS.** Dislocation generation and the reactions during the crystal growth in undoped and In-doped GaAs have been investigated, and the formation mechanism of lineage structures in undoped crystals is discussed. Rectangular specimens were plastically bent with the same stress directions as those expected during crystal growth. The dislocation distribution in the deformed crystals was compared with that in an as-grown In-doped crystal. By considering the slip systems acting in the crystals, it was found that different kinds of dislocation reactions occur depending on the azimuth at the wafer periphery. Slip dislocations around  $\langle 110 \rangle$  directions react to form sessile dislocations along the dislocation propagation direction. It is concluded that this is an early stage of lineage formation, which extends along  $\langle 110 \rangle$  at the  $\langle 110 \rangle$  region. (Author abstract) 19 refs.

**093994 A GROWTH ANALYSIS FOR METAL-ORGANIC VAPOR PHASE EPITAXY OF GaAs.** Metalorganic vapor phase epitaxy (MOVPE) of GaAs is analyzed using a new growth model. Surface reactions for trimethylgallium or triethylgallium adsorbed on the substrate surfaces are assumed to be the growth-rate-limiting steps. A catalytic effect is taken into account by assuming different decomposition rates for adsorbed alkyls on Ga- and As-terminated surfaces. The surface reactions are expressed in terms of reaction times and analyzed using a rate equation approach. Parameters in a rate equation are determined by fitting to the experimental results obtained by various methods: conventional MOVPE with and without laser irradiation, pulsed MOVPE, and laser atomic layer epitaxy. Good agreement between experiments and calculations in all growth methods shows the usefulness of the model. (Author abstract) 12 Refs.

**093995 SELECTIVELY DOPED GaAs/N-Al<sub>0.3</sub>Ga<sub>0.7</sub>As HETEROSTRUCTURES GROWN BY GAS-SOURCE MBE.** Selectively doped GaAs/N-Al<sub>0.3</sub>Ga<sub>0.7</sub>As heterostructures with a 6 nm spacer layer have been grown for the first time by gas-source MBE using

triethylgallium and triethylaluminum as group III sources, and metallic arsenic. A reasonably high two-dimensional electron gas (2DEG) mobility of  $48,000 \text{ cm}^2/\text{Vs}$  (77 K) with a sheet electron concentration ( $N_s$ ) of  $6.8 \times 10^{11} \text{ cm}^{-2}$  was obtained at a substrate temperature of  $580^\circ\text{C}$  and an arsenic pressure of  $1.1 \times 10^{-4}$  Torr. (Author abstract) 13 Refs.

**093996 BEHAVIOR OF Ge DURING LPE GROWTH OF GaAs.** The incorporation behavior and the ratio of Ge on Ga site to Ge on As site during GaAs LPE growth have been studied in a temperature range of  $550\text{--}950^\circ\text{C}$  by means of Hall measurement, SIMS, electrochemical C-V and photoluminescence. The segregation coefficient of Ge rises as the temperature decreases and the ratio of  $\text{Ge}_{\text{Ga}}/\text{Ge}_{\text{As}}$  increases with temperature in the range of  $550\text{--}950^\circ\text{C}$ . (Edited author abstract) 14 Refs. In Chinese.

**093997 EPITAXIAL METASTABLE (GASB)<sub>1-x</sub>(Ge<sub>2</sub>(1-y)Sn<sub>2</sub>)<sub>x</sub> QUATERNARY ALLOYS ON GAAS(100): CRYSTAL GROWTH, STRUCTURE, AND RAMAN SCATTERING.** Epitaxial metastable (GaSb)<sub>1-x</sub>(Ge<sub>2</sub>(1-y)Sn<sub>2</sub>)<sub>x</sub> quaternary alloys have been grown with  $0 \leq x \leq 1$  and  $y \leq 0.27$  by RF multitarget sputter deposition on GaAs(100) substrates. Films,  $\approx 1 \mu\text{m}$  thick, deposited under the same growth conditions on Corning 7059 glass substrates were polycrystalline with a strong (220) preferred orientation. A growth phase map, plotted as a function of x, y, and deposition temperature  $T_s$ , showed that the maximum growth temperature decreased rapidly with increasing Sn concentration, ranging from  $\geq 500^\circ\text{C}$  for  $0 \leq x \leq 1$  with  $y=0$  to  $\geq 150^\circ\text{C}$  for  $x=0.6$  with  $y=0.27$ . The lattice parameter  $a_0$  of the alloys decreased linearly with increasing x for a given y and increased linearly with y for a given value of x.  $a_0$  ranged from  $0.6094 \text{ nm}$  for GaSb to  $0.5775 \text{ nm}$  for (GaSb)<sub>0.2</sub>(Ge<sub>1.86</sub>Sn<sub>0.14</sub>)<sub>0.8</sub>. Analysis of fundamental and superstructure diffraction peak intensities, the zincblende-to-diamond structure phase transition was found to occur near  $x \approx 0.3$ . Raman scattering results showed a two-peak behavior over the composition range investigated. The GaSb-like longitudinal-optical peak near  $234 \text{ cm}^{-1}$  softened and broadened with increasing x for all y values. A weak 'Ge-like' mode increased in frequency from  $265 \text{ cm}^{-1}$  at  $x=0.05$  with  $y=0.07\text{--}0.27$  to  $280 \text{ cm}^{-1}$  at  $x=0.6$  and  $y=0.07$ . The reaction path for phase decomposition in these alloys was found using hot-stage transmission electron microscopy to proceed through a series of intermediate metastable phases. (Edited author abstract) 26 Refs.

**093998 GROWTH AND ASSESSMENT OF CDS AND CDSE LAYERS PRODUCED ON GAAS BY METALORGANIC CHEMICAL VAPOR DEPOSITION.** CdS and CdSe layers have been grown successfully on GaAs by MOCVD. The surface morphology, RHEED patterns and photoluminescence properties of the layers were studied for different substrate orientations. It was found that the CdS grew hexagonally on the (111)A substrate face, while the layers produced on (100), (110) and (111)B faces were a mixture of cubic and hexagonal phases. Layers of CdSe grown on GaAs were also a mixture of cubic and hexagonal phases for substrate faces other than (111)A, for which the layer was predominantly cubic. The change in photoluminescence with growth temperature was investigated and for CdS the best growth temperature, as measured by the width of the bound

exciton emission, was 350°C. No evidence of large scale diffusion of Ga or As from the substrate was found. (Author abstract). 14 Refs.

**093999 TYPES OF OVAL DEFECTS ON GAAS GROWN BY MBE.** According to the shapes of oval defects, three types are observed on the MBE grown GaAs epilayers. All of their long oval axis were along the  $\langle 110 \rangle$  direction, but their origins are attributed to different sources. The origins of each type are deduced by experiments. The composition of the oval defects is similar to that of the grown epi-layers by the analysis of EDAX. (Edited author abstract). 11 Refs.

**094000 DYNAMICS AND CONTROL OF THE CZOCHRALSKI PROCESS. II. OBJECTIVES AND CONTROL STRUCTURE DESIGN.** A new control system design is proposed for the Czochralski process in order to improve crystal quality, particularly GaAs. An expanded set of formal control objectives are proposed based on a consideration of defect formation, segregation, and the process coupling. A control structure is developed that meets the control objectives and the restrictions posed by the batch related disturbances, system coupling, and the dynamic characteristics of the measurements, outputs, and inputs. (Author abstract). 42 Refs.

**094001 TEMPERATURE GRADIENTS, DOPANTS, AND DISLOCATION FORMATION DURING LOW-PRESSURE LEC GROWTH OF GaAs.** In this work we will review the current status of low pressure, low thermal gradient GaAs crystal growth. Our previous studies have shown that undoped GaAs crystals grown under low pressure by the liquid encapsulated Czochralski technique from melts with axial temperature gradients of 6°C/cm at the solid/liquid interface have dislocation densities of approx.  $3 \times 10^3 \text{ cm}^{-2}$  throughout the boule. Our recent work shows that growth at an order of magnitude slower pull rate has no effect on this dislocation density, but does result in more extensive polygonization. Increased pull rates, however, increase the dislocation density. These observations together with others reported in the literature strongly support a mechanism wherein dislocations are formed as a result of microscopic stress fields (exceeding the critical resolved shear stress) that arise from inhomogeneous vacancy incorporation at the solid/liquid interface. (Edited author abstract) 36 refs.

**094002 GROWTH AND CHARACTERIZATION OF LOW DEFECT GaAs BY VERTICAL GRADIENT FREEZE.** In this paper we discuss the growth of 2 inch diameter undoped and In-alloyed GaAs by vertical gradient freeze (VGF). Through the use of low gradients, undoped material with a dislocation density of  $(2-6) \times 10^3 \text{ cm}^{-2}$  has been obtained. With the addition of 0.6 at.% InAs to the melt, this density is further reduced to 0-1000  $\text{cm}^{-2}$ . In contrast to standard LEC, GaAs grown by VGF shows low concentrations of the EL2 deep level and of the C shallow acceptor level. The material is semi-insulating,  $\rho \geq 10^7 \Omega \text{ cm}$ , and is thus suitable for device applications. From temperature dependent Hall measurements, the semi-insulating (SI) behavior is believed to be caused by Fermi level pinning at a defect with an energy level of approx. 0.5 eV. (Edited author abstract) 15 refs.

USA); Kinsella, A.P.; Jordan, A.S.; Caruso, R.; Pearton, S.J.; Temkin, H.; Wade, H. *J Cryst Growth* v 85 n 1-2 Nov 1 1987, Amer Cryst Growth 1987, Proc of the Seventh Amer Conf on Cryst Growth, Monterey, CA, USA, Jul 12-17 1987 p 106-115.

**094003 GROWTH AND CHARACTERIZATION OF GaAs ALLOYED WITH IN AND P.** Indium- and phosphorus-alloyed GaAs crystals were grown by the liquid encapsulated Czochralski (LEC) method. Phosphorus was found to complement indium, which has relatively low concentration at the seed end, in providing the lattice hardening. The dislocation density was low even at the seed end of the crystals. Lattice-matched wafers exhibited near zero band gap shift in the crystal where the ratio of phosphorus to indium ranged from 1 to 1.3. The distribution coefficient of phosphorus was determined to be 3.  $0 \pm 0.3$  for the two crystals grown at 2 and 4 mm/h. The crystals exhibited high room-temperature electron mobility of  $> 7000 \text{ cm}^2/\text{V}\cdot\text{s}$  and resistivities ranging from low  $10^7$  to low  $10^8 \Omega \text{ cm}$ . Temperature-dependent Hall measurements revealed no extraneous levels attributable to indium or phosphorus in the band gap. (Author abstract) 17 refs.

**094004 EVALUATION OF THE MELLER 'EDG' FURNACE FOR GROWTH OF LARGE DIAMETER GaAs SINGLE CRYSTALS IN A HORIZONTAL CONFIGURATION.** An extensive evaluation of the Meller 'EDG' furnace has been conducted in order to assess its performance for growth of large diameter (2 and 3 inch) GaAs crystals in the horizontal configuration. The axial and radial temperature gradients were found to influence strongly the crystal-melt interface shape and crystalline perfection of the crystals. When the axial thermal gradients are small relative to the radial thermal gradients, the shape of the crystal-melt interface fluctuates in time as growth proceeds, indicating the presence of oscillatory convective flows in the melt. The crystal-melt interface becomes stable as the axial component of the thermal gradient over the solid is increased. The crystals produced with optimized gradient conditions have a low and uniform dislocation density. (Author abstract) 11 refs.

**094005 GROWTH AND CHARACTERIZATION OF HIGH QUALITY LPEE GaAs BULK CRYSTALS.** High purity GaAs bulk crystals were grown by liquid phase electroepitaxy (LPEE). One inch diameter more than 4 mm thick ingots were free of polycrystalline edges and Ga inclusions. Typical free carrier concentration was in the  $10^{14} \text{ cm}^{-3}$  range. Low temperature photoluminescence (PL) measurements identified the Si acceptor as the dominant residual impurity which was distributed very uniformly throughout the ingots. In addition, a correlation was established between residual impurity concentration and key growth parameters, such as temperature, baking time of the Ga-As solution, and the solution volume. **094006 EFFECT OF CRYSTAL RADIUS FLUCTUATIONS ON THE STRESS FIELD IN LEC GALLIUM ARSENIDE.** Calculations of the shear stress field in LEC Gallium Arsenide have been carried out in which the crystal radius was systematically changed during growth. Various combinations of wavelength and amplitude of fluctuations were considered both in the bulk

crystal and the seeding cone. For the bulk crystal, the maximum shear stress is shown to increase as the amplitude of the fluctuations increases and the wavelength decreases. For fluctuations with wavelengths less than 20 mm, the shear stress increases hyperbolically with decreasing wavelength. Fluctuations in radius in the seeding cone result in higher stresses in the cone, but these stresses do not reach the stresses in the bulk crystal. (Author abstract) 9 refs.

**094007 COMPLEX FLOW PHENOMENA IN VERTICAL MOCVD REACTORS: EFFECTS ON DEPOSITION UNIFORMITY AND INTERFACE ABRUPTNESS.** The structure of axisymmetric flow patterns in vertical MOCVD reactors is studied with emphasis on their effect on deposition rate uniformity and interface abruptness. Flow visualizations by illuminating  $\text{TiO}_2$  seed particles in a sheet of laser light are used to illustrate forced and mixed convection flows. Excellent agreement between experimental observations and model predictions is demonstrated. Simulations show that the film thickness uniformity is affected by susceptor edge, reactor wall and buoyancy effects. Furthermore, nonlinear interactions between transport processes lead to multiple steady flows for typical operating conditions. The deposition of GaAs and AlAs from  $\text{Ga}(\text{CH}_3)_3$ ,  $\text{Al}(\text{CH}_3)_3$  and  $\text{AsH}_3$  are used as case studies. Simulations of solid and gas phase concentration transients in the growth of AlAs/GaAs interfaces illustrate the effects flow structures have on interface abruptness. (Author abstract) 24 refs.

**094008 IN SITU MASS SPECTROSCOPY AND THERMOGRAVIMETRIC STUDIES OF GaAs MOCVD GAS PHASE AND SURFACE REACTIONS.** Two special MOCVD reactors systems designed for in situ monitoring of gas phase and surface reactions are presented. The gas phase decomposition mechanisms of  $\text{Ga}(\text{CH}_3)_3$ ,  $\text{Ga}(\text{C}_2\text{H}_5)_3$  and  $\text{As}(\text{CH}_3)_3$  in  $\text{H}_2$ , He and  $\text{D}_2$  are investigated by molecular beam sampled mass spectroscopy. The data show that the initial thermal pyrolysis reaction of  $\text{Ga}(\text{CH}_3)_3$  and  $\text{As}(\text{CH}_3)_3$  is a unimolecular reaction leading to the loss of methyl groups. A new thermogravimetric MOCVD system is used to measure surface reaction rates of  $\text{Ga}(\text{CH}_3)_3$  and  $\text{As}(\text{CH}_3)_3$  at low pressures, where mass transfer effects are absent. Data for varying total pressures and constant partial pressures of  $\text{Ga}(\text{CH}_3)_3$  and  $\text{As}(\text{CH}_3)_3$  indicate that the growth rate at reduced pressures is influenced by gas phase reactions. At low pressures surface reactions appear to dominate and at high temperatures the growth rate goes to zero and etching takes place. (Edited author abstract) 31 refs.

**094009 LIQUID PHASE EPITAXY OF GaAs QUANTUM WELL STRUCTURES.** Gallium arsenide quantum wells are grown by liquid phase epitaxy. The growth parameters are carefully adjusted in order to prevent any dissolution of the GaAlAs layer by the GaAs growth solution as well as to eliminate solution carryover. The interfaces between the thin GaAs layer and the GaAlAs cladding layers are therefore chemically abrupt. Due to a specific difference in the growth morphologies of GaAlAs and GaAs, the GaAlAs/GaAs and the GaAs/-

GaAlAs heterointerfaces differ considerably. The different interface morphologies cause quantum well thickness fluctuations which influence the line-widths of the quantum well related optical transitions. Photoluminescence measurements presently reveal minimum line-widths of 2.5 meV, and discrete  $n=1$  heavy-hole,  $n=1$  light-hole, and  $n=2$  heavy-hole exciton transitions are clearly detected by photoluminescence-excitation spectroscopy. (Author abstract) 13 refs.

**094010 GROWTH AND CHARACTERIZATION OF GaAs ON Si SUBSTRATES GROWN BY MOLECULAR-BEAM EPITAXY.** Single-crystal GaAs layers have been grown by molecular beam epitaxy (MBE) on (100) Si substrates. Surface morphology, defect density, and optical and electrical properties have been studied as a function of the growth parameters. The characterization techniques included photoluminescence, Hall effect, cross-sectional transmission electron microscopy, and X-ray diffraction. GaAs metal semiconductor field-effect transistors on Si exhibited transconductances of  $128 \text{ mS} \cdot \text{mm}^{-1}$  and current-gain cutoff frequencies as high as 19 GHz. Special heterostructures showed Shubnikov-de Haas oscillations at low temperature and plateaus in the Hall resistance, which confirmed the presence of two-dimensional electron gas in the heterostructure. (Author abstract) 28 refs.

**094011 GROWTH OF GALLIUM ARSENIDE ON Si(100) BY MOLECULAR-BEAM EPITAXY.** The growth of GaAs on Si(100) directly and with Ge buffer layers has been carried out sequentially under ultra high vacuum conditions in a double-ended III-V and group IV molecular beam epitaxy system. These heterostructures were examined by cross-sectional transverse emission microscopy, Rutherford backscattering, X-ray diffraction, and photoluminescence spectroscopy. Dislocation densities were observed to be high ( $\geq 10^9 \text{ cm}^{-2}$ ) near both the GaAs-Si and the Ge-Si interfaces and to decrease to approximately  $5 \times 10^8 \text{ cm}^{-2}$  a few micrometers from these interfaces. No dislocations were observed to originate at the GaAs-Ge interface, but the threading dislocations existing in the Ge buffer layer were found to propagate across this interface without significant deviation. The crystalline quality of the GaAs grown on Ge buffer layers was comparable with that grown on Si directly. (Author abstract) 11 refs.

**094012 GROWTH AND PROPERTIES OF  $\text{Ga}_{1-x}\text{In}_x\text{As}$  STRAINED LAYER SUPERLATTICES GROWN BY LOW-PRESSURE METAL-ORGANIC VAPOUR-PHASE EPITAXY.** We have analyzed the structural and optical properties of  $\text{Ga}_{1-x}\text{In}_x\text{As}$ -GaAs strained-layer superlattices (SLS) grown by low-pressure metal-organic vapour-phase epitaxy. Sample uniformity over  $2.5 \text{ cm} \times 2.5 \text{ cm}$  has been studied by X-ray diffraction and low-temperature photoluminescence. The sample composition and period are uniform in the longitudinal direction (gas-flow direction in the reactor) and in the central portion (1.5 cm) in the transverse direction. On each side, the In composition decreases slightly towards the edges, as shown by an energy shift of the photoluminescence excitonic recombinations. Comparison of experimental and calculated transition energies in a series of samples, taking into account strain and

quantization, shows clearly that SLS grown on mismatched buffer layers are under additional strain. This additional strain is not present when the layer or whole SLS thicknesses exceed a critical value beyond which the mismatch is partially accommodated by misfit dislocations. (Author abstract) 17 refs.

**094013 STRUCTURE OF HETEROEPITAXIAL GaAs ON Si.** We present x-ray scattering results which indicate that thin GaAs films are compressed in the film plane at room temperature, while thicker films are under tensile stress, the cross-over region being at about 1000 Å. In addition, we show that the GaAs lattice is translationally incommensurate with the Si substrate and that the in-plane [001] axes are misaligned by 3-5°. Thermal expansion measurements of the out-of-plane lattice parameters of the film and substrate indicate that the GaAs in-plane thermal expansion follows from the anharmonicity of the substrate. (Edited author abstract) 8 refs.

## Halogenation

**094014 FLUORINATION OF GaAs.** [Fluorination of GaAs]. Coating layers were grown on GaAs (100) by oxidation under fluorine of the semiconductor. For a fluorination temperature close to 400°C and a fluorine pressure of 1 bar, Rutherford backscattering (RBS) of 2 MeV  $\alpha$  particles and infrared measurements show that the inner part of the layers is mainly constituted of the fluoride of III-B element. However XPS studies performed on very thin layers (40 Å-50 Å) reveal that arsenic as gallium is always present near the interfaces and is bound with fluorine. At room temperature for a sweep frequency down to 0.01 Hz, the 1 MHz C(V) characteristics show that an important modulation of the surface potential of the semiconductor is obtained without hysteresis. (Author abstract) 3 refs. In French.

**094016 MULTIPLE STRUCTURES OF TRANSITION-METAL DEEP IMPURITIES IN GaAs.** The multiplet structures of substitutional 3d transition-metal (TM) impurities Ti to Ni in GaAs have been calculated by the first-principles cluster method, which connects the calculated results of the one-electron energy levels by the LDA approach on the cluster consisting of 59 atoms with the ligand-field theory of Sugano, Tanabe and Kamimura. The present theory explains fairly well experimental results on the low-lying multiplets of various TM impurities in GaAs and also reproduces qualitatively the observed chemical trend seen in the ionization energies of TM impurity acceptors. (Author abstract) 20 refs.

**094018 SEM AND EMPA ANALYSIS OF IMPURITIES RELATED TO GaAs SUBSTRATES AND MBE GROWN GaAs LAYERS.** Distribution of impurities on heat-treated GaAs substrates and layers has been investigated by SEM in conjunction with EMPA analysis. The layers were grown by MBE on both undoped and chromium doped semi-insulating substrates. Comparisons of the electron micrographs and the corresponding EMPA spectra suggest that heating causes the impurities, namely Si, Fe and Cr, to diffuse out from the substrate and redistribute themselves on the layer surface resulting in characteristic defect patterns. No effects due to arsenic over-pressure and/or presence of carbon in the growth environment were apparent, as suggested by previous studies. (Author abstract) 10 refs.

**094019 SUBSTRATE-IMPURITIES EFFECTS ON GaAs MESFETs.** The effects of background impurities in LEC and HB-grown, doped and undoped GaAs substrates on electron-concentration profiles and ion-implanted MESFET threshold voltages are modeled. For realizing the most steeply falling channel electron profiles, high concentrations of either deep or shallow acceptors are required. When background acceptor impurities are absent, the electron profiles follow the slowly falling ion-implant profiles, which are strongly influenced by ion channeling. The use of buried p layers to give steeply falling profiles, and to reduce the dependence of MESFET threshold voltages on fluctuating acceptor impurities in GaAs is proposed. (Author abstract) 28 refs.

**094020 APPROXIMATE TREATMENT OF LOCALIZED VIBRATIONAL MODES.** The 'rigid-well' approximation for the local vibrational mode frequency of a light impurity in a crystal in which only the impurity itself is regarded as moving may be regarded as the leading term in an expansion in powers of the ratio of the impurity mass to the host mass or masses. It is found that the retention of only one further term provides an analytic approximation that is quantitatively useful over a much wider range of cases of interest. This approximation

assumes a particularly simple form if the contributions from the motion of second and further neighbors of the impurity are negligible. Various applications are presented. (Author abstract) 22 refs.

**094021 DETERMINATION OF THE RESIDUAL CARBON ACCEPTOR CONCENTRATION IN SEMI-INSULATING GaAs WAFERS BY IR SPECTROSCOPY: ACCURACY AND DETECTION LIMITS.** The IR absorption method is investigated in detail with respect to a routine application in semiconductor industry laboratories. The experimental and analytical procedures necessary for an accurate determination of the residual carbon acceptor ( $C_A$ ) concentration also in commercial wafers are given. A specific technique to eliminate the interference fringes arising from multiple reflections inside the wafer is presented. At a measurement temperature of 77 K the detection limit for carbon is  $6 \times 10^{13} \text{ cm}^{-3}$  in wafers of 5 mm thickness. The IR method is also applicable to commercial wafers giving a detection limit of about  $6 \times 10^{14} \text{ cm}^{-3}$ . (Author abstract) 18 refs.

**094022 DEFECT INDUCED RAMAN TRANSITION IN NON-STOICHIOMETRIC Ga-RICH GaAs: A PSEUDOLocalized VIBRATIONAL MODE OF THE GaAs ANTISITE?** Raman scattering with below band gap excitation has been used to study as grown GaAs pulled from Ga-rich melts. A vibrational pseudolocalized defect mode is observed at  $225 \text{ cm}^{-1}$  in material, which also contains the 78/203 meV double acceptor. The temperature variation of the  $225 \text{ cm}^{-1}$  Raman peak is found to depend on the charge state of the double acceptor. These findings indicate that the 78/203 meV acceptor levels and the  $225 \text{ cm}^{-1}$  vibrational mode may arise from the same defect center. Possible models for this center are discussed including the Ga-antisite defect. (Author abstract) 14 refs.

**094024 IMPURITY BANDS IN  $\text{Ga}_{1-x}\text{Al}_x\text{As}/\text{GaAs}$  QUANTUM WELLS.** We calculate the Density-of-States (DOS) for electrons bound to impurities in a thin sheet inside a  $\text{Ga}_{1-x}\text{Al}_x\text{As}/\text{GaAs}$  quantum well. Impurities are considered at the center, midway to the interface and at the interface of the GaAs layer. It is shown that for reasonable impurity concentrations an impurity band appears separated from the lowest subband. The bandwidth is comparable with that obtained due to diagonal disorder assuming a uniform distribution inside the whole well. (Author abstract) 6 refs.

**094026 EFFECTS OF SUBSTRATE MISORIENTATION AND GROWTH TEMPERATURE ON IMPURITY INCORPORATION IN HYDROGEN REDUCTION CHLORIDE VPE OF GaAs.** Effects of misorientation of the substrate and growth temperature on the carrier concentration were investigated for the epitaxial growth of GaAs by chloride vapor phase epitaxy (VPE) utilizing the hydrogen reduction method. Carrier concentrations of the epitaxial layers grown on  $2^\circ$  off (100) substrates are always about one half of those on exactly (100) substrates, even though the compensation ratios are the same. The carrier concentration and the total impurity incorporated increase monotonically with increase of the growth temperature, but the compensation ratio is a minimum at a growth temperature of  $750^\circ\text{C}$  and increases at higher and lower growth temperatures. These results seem to be explained by the Kossel model, i.e. by smaller segregation constants of the impurities for  $2^\circ$  off (100) substrates with many growth steps. (Author abstract) 18 refs.

**094027 THEORY OF IMPURITY BAND RECOMBINATION.** Multiple scattering theory (MST) according to Klauder applied to the energy spectrum of a semiconductor enables the description of the extreme case of heavily doped as well as of slightly doped material. For doping levels of donors and acceptors below the Mott density the MST provides an impurity band state density for electrons and holes and an almost parabolic conduction and valence band state density. In the framework of this procedure we have calculated the whole luminescence spectrum of GaAs. The considered doping is of n-type ( $N_D = 5 \times 10^{14} \text{ cm}^{-3}$ ), where the degree of compensation of the material is assumed to amount to 10%. The theoretical results are compared with measured luminescence spectra. (Author abstract) 5 refs.

**094029 PROPERTIES OF THE 78 meV ACCEPTOR IN GaAs.** An acceptor with a binding energy of 78 meV is frequently observed in LEC GaAs. As a commonly observed acceptor its identification and control are important aspects of materials development. It has recently been

shown to be a double acceptor with a second level at 203 meV. Although it is a common center its origin has not yet been conclusively determined; both the gallium antisite and boron on the arsenic site are often proposed origins. Experimental and theoretical studies of this acceptor are reviewed including the identification of the center as a double acceptor, the origins of the various photoluminescence properties, infrared absorption by the electronic levels of this impurity, Raman studies of the S-states, and experiments bearing on its identification. (Author abstract) 27 refs.

**094030 OPTICAL AND ELECTRICAL STUDIES OF LIQUID-ENCAPSULATED CZOCHRALSKI SEMI-INSULATING GaAs WITH DIFFERENT CARBON CONCENTRATIONS.** The effects of the presence of carbon over a range of approximately  $10^{14}$ - $10^{16} \text{ cm}^{-3}$ , in liquid-encapsulated Czochralski-grown semi-insulating GaAs have been studied using Fourier-transform infrared (FTIR), photoluminescence, and photo-induced transient spectroscopy (PITS), and temperature-dependent Hall-effect measurements. From photoluminescence measurements in the temperature range of 4-30 K, the decay signal was found to consist of two parts, the initial decay obeying an exponential behaviour with an activation energy of 15 meV and the subsequent decay obeying a power law of the form  $t^{-P}$  with the values of  $P$  ranging from 1.4 to 3.5. Results from PITS measurements revealed a broad peak at about 240 K which could be due to the formation of a free As vacancy or its complexes. The intensity of the EL2 family of emission peaks was directly dependent on the water content of the boric oxide encapsulant used during the growth process. Mobility and resistivity of the samples were also measured and tabulated. (Edited author abstract) 17 refs.

**094031 INVERTED POPULATIONS OF HOT ELECTRONS IN A MAGNETIC FIELD: THE EFFECTS OF ELECTRON-ELECTRON AND IMPURITY SCATTERING IN n-GaAs.** Monte Carlo simulation of hot-electron transport in bulk n-GaAs in the presence of crossed electric and magnetic fields shows that inverted populations associated with cyclotron motion can arise at low temperatures provided charged impurity scattering is weak. Electron-electron scattering, even at electron concentrations as low as  $10^{14} \text{ cm}^{-3}$ , at 10K limits the range of electric fields over which inversion occurs. Strong negative magnetoresistance, though weakening, persists to 300K, even in the presence of an impurity and electron concentration of  $2 \times 10^{17} \text{ cm}^{-3}$ , and dynamic screening of the polar interaction. (Author abstract) 9 refs.

**094032 THERMAL DIFFUSION OF BURIED BERYLLIUM AND SILICON LAYER IN GaAs DOPED BY FOCUSED ION BEAM IMPLANTATION.** The diffusion profiles of buried Be and Si doped by focused ion beam (FIB) implantation in GaAs after annealing were investigated. The diffusion coefficients of Be and Si were determined by fitting from the results of computer calculations. The diffusion coefficient of FIB-doped Be was enhanced by excess interstitial Be. Beryllium diffusion profiles expand by annealing with a high dose of 850°C. The concentration-dependent diffusion of Si in GaAs doped using a molecular beam was observed. The diffusion coefficient of Si heavily doped by FIB, however, was undetectably small in contrast with that of Be at 850°C. (Author abstract) 12 refs.

**094035 SUBSTRATE IMPURITY MIGRATION DURING RAPID THERMAL ANNEALING OF SI IMPLANTED GaAs.** One of the potential advantages of rapid thermal annealing (RTA) compared to conventional furnace annealing is reduced implant dopant and background impurity diffusion. In this paper, the migration of Cr and Mn during annealing of Cr-doped semi-insulating GaAs implanted with 100 Kev Si<sup>+</sup> ions at a dose of  $7 \times 10^{12} \text{ cm}^{-2}$  was measured using SIMS. We investigated uncapped RTA at 860° and 930°C for times between 1 and 60s and compared them to capless 30 min furnace anneals. During RTA, Cr migration was severe and showed a strong time-temperature dependence. Mn migration was undetectable for RTA anneals less than 60s, but dominated the 30 min furnace anneals. (Author abstract) 9 refs.

**094036 TRANSIENT ANNEALING OF HIGH DOSE Mg IMPLANTS IN GaAs.** Transient anneals of high dose ( $10^{15} \text{ cm}^{-2}$  at 150 keV) Mg implants in GaAs showed a maximum in sheet carrier density of  $2.1 \times 10^{14} \text{ cm}^{-2}$  at 750°C/5 s. Close correlation of carrier concentration vs. depth profiles with atomic concentration vs. depth

profiles strongly indicated that the electrical behavior of the implant is governed by redistribution of the implant; up to 50% of the total dose being lost to the cap after a transient anneal at 900°C/5 s. (Author abstract) 14 refs.

**094037 SILICON NITRIDE FILM AS GaAs ANNEALING ENCAPSULANT.** Doping GaAs wafers using ion implantation is widely used in the semiconductor industry. Because of the damage caused by this procedure, the wafer must be annealed at temperatures approaching 900°C. This relieves the stress and damage in the wafer caused by the ions, and activates the implant. To avoid dissociation of the gallium and arsenic at these elevated temperatures, the wafer is enveloped in a dielectric sheath which acts as a diffusion barrier. This film must offer good adhesion to the substrate, be free of pinholes, have excellent thermal cycling properties and still act as a diffusion mask against Ga and As. Such a film offers additional physical protection during handling and subsequent photolithography. The dielectric must also be of such a quality that after all this processing it can be removed easily. Silicon dioxide, oxynitride and nitride have been used as encapsulants on III-V materials. This article concentrates on silicon nitride and investigates its behavior during annealing. 7 refs.

**094039 LASER ANNEALING OF GaAs IMPLANTED WITH LOW DOSES OF SELENIUM IONS.** GaAs samples were implanted with 100-400 keV,  $10^{12}$ - $10^{14} \text{ cm}^{-2} \text{ Se}^+$  ions and annealed using undiffused and diffused pulsed ruby-laser beams with the samples held at various temperatures. The resulting surface and structural defects as observed by various microscopic and spectroscopic methods are related to measured electrical properties of implanted GaAs, and the causes of the observed poor and lack of electrical activation of samples identified. Laser irradiation of samples ( $T \approx 516^\circ\text{C}$ ) induces surface damage in the form of regular parallel broken lines with a periodicity of about 0.69  $\mu\text{m}$ , the wavelength of the ruby laser. A diffused laser beam ( $\leq 0.5 \text{ J/cm}^2$ ) reduces surface vaporization and eliminates periodic surface structures. The measured electrical properties are still poor. (Author abstract) 20 refs.

**094040 DAMAGE DISTRIBUTION IN Si<sup>+</sup>-IMPLANTED GALLIUM ARSENIDE-LATTICE IMAGING.** Silicon-implanted GaAs is studied by cross-sectional high-resolution transmission electron microscopy. A diffusion zone, next to the maximum of radiation-defect clusters, distribution with an extension of 200-300 Angstrom has been observed. The changes of the contrast are interpreted as related with radiation-enhanced diffusion of As interstitials. (Author abstract) 14 refs.

Vitali, G. (Univ of Rome 'La Sapienza', Rome, Italy); Kalitzova, M.; Pashov, N.; Werner, P.; Bartsch, H. *Appl Phys A* v 45 n 2 Feb 1988 p 133-135.

**094041 TRANSIENT ANNEALING OF Sn<sup>+</sup> IM-**

**PLANTED GaAs.** High temperature ( $\geq 900^\circ\text{C}$ ) transient annealing of Sn<sup>+</sup> implants into GaAs have been studied by secondary ion mass spectroscopy, electrical measurements and transmission electron microscopy. A two-layer encapsulant ( $\text{Si}_3\text{N}_4 + \text{AlN}$ ) has been used prior to annealing using an incoherent light furnace. Secondary ion mass spectroscopy measurements show that outdiffusion of tin has occurred which depends both on the dose and annealing conditions. The as implanted atomic profiles are wider than the theoretical profiles and up to 17% further broadening occurs during annealing. Electron concentrations approach  $10^{19} \text{ cm}^{-3}$  have been measured reproducibly. Transmission electron microscopy results show both faulted and unfaulted dislocation loops and dislocation lines, all defects being decorated with precipitates which contain metallic tin. A large concentration of stacking fault tetrahedra is also produced. (Author abstract) 12 refs.

Shahid, M.A. (Univ of Surrey, Guildford, Engl); Bensalem, R.; Sealy, B.J.; Favennec, P.N.; Gauneau, M. *Nucl Instrum Methods Phys Res Sect B* v B30 n 4 Apr 1 1988 p 531-539.

**094042 MeV S IMPLANTATION INTO GaAs.** The physical and electrical characteristics of MeV S implants into GaAs have been studied. The redistribution of the ion implanted S has been investigated using secondary ion mass spectroscopy and electrochemical capacitance-voltage profiling. The redistribution of the implanted S has been greatly reduced when rapid thermal anneal, instead of furnace anneal, is employed for activation. The measured diffusion coefficient (using RTA) is  $3.7 \times 10^{-12} \text{ cm}^2/\text{s}$ , which is comparable to that measured in furnace annealed samples. Hence the reduction in the redistribution is solely from a reduction of the time at temperature. (Edited author abstract) 26 refs.

**094043 COMPOSITION AND CARBON EFFECTS ON UNIFORMITY FOR IMPLANTED ACTIVE LAYERS FABRICATED IN UNDOPED LEC GaAs.** Fluctuations in carrier concentrations in implanted layers were found to depend on the carbon concentration in substrates. Real composition effects, i.e. not via carbon, were clarified, when the carbon concentration was reduced to  $\approx 3 \times 10^{14} \text{ atoms/cm}^3$ . Fluctuations in the carrier concentration were least, when a crystal was grown from raw materials with an atomic ratio (Ga/As)<sub>m</sub> around 0.95. (Author abstract) 4 refs.

Usuda, K. (Toshiba Corp, Kawasaki, Jpn); Yasuami, S. *Mater Lett* v 6 n 5-6 Mar 1988 p 164-166.

**094044 ANNEALING BEHAVIOUR OF Be- AND Mg-IMPLANTS IN GaAs.** Mg<sup>+</sup> and Be<sup>+</sup> ions were implanted into semi-insulating GaAs with doses ranging from  $10^{14}$  to  $2 \times 10^{15} \text{ cm}^{-2}$ . Both implants were annealed by furnace anneal (FA) as well as by rapid thermal anneal (RTA) with various annealing temperatures and were analyzed by Secondary Ion Mass Spectroscopy (SIMS), Hall and electrochemical carrier profile measurements. Both Mg and Be as-implanted profiles can be fitted by Pearson-IV distributions. After RTA SIMS measurements show significant diffusion only for high-temperature anneals. In this case Be exhibits large diffusion tails and distinct steps in the atomic profile, whereas Mg shows only a slight dopant redistribution. However, after FA generally strong dopant redistribution and surface peaks can be observed. Mg implants yield lower activation and higher sheet resistances than Be when identical implantation doses and annealing cycles are used. (Author abstract) 18 refs.

**094047 IMPLANTATION IONIQUE A HAUTE ENERGIE DU SI DANS L'AsGa. [High-Energy Implantation of Si Ions in GaAs].** We present a study of the implantations of 7 MeV Si ions into GaAs at a dose of  $10^{14}$  ions/cm<sup>2</sup>. The depth profile of the ions is measured by secondary-ion mass spectroscopy. It is found to be in good agreement with a Monte Carlo calculation based on the Lindhard, Scharff and Schiott model of ion collisions in solids. The penetration depth of the Si ions is 3.38  $\mu$ m, with a standard deviation 0.35  $\mu$ m. The samples are annealed in a rapid annealing oven. A maximal activation of dopants is obtained with a temperature of 850°C for 20 s. The resistivity and average mobility after this anneal are  $3.48 \times 10^{-3}$   $\Omega$ -cm and 2800 cm<sup>2</sup>V<sup>-1</sup>s<sup>-1</sup> respectively. This suggests that the majority of ions are activated. (Author abstract) 8 refs. In French.

## Ionization

**094049 ELECTRON IONIZATION RATE IN MULTILAYERED SEMICONDUCTOR STRUCTURES.**

We present theoretical results of the electron impact ionization rate in GaAs/AlGaAs multi-quantum-well structures as a function of applied electric field for various geometries, i.e., well and barrier widths. In addition, we present preliminary measurements of the current-voltage characteristics of MBE-grown photodiodes which demonstrate very low leakage current as well as sharp breakdown behavior. It is found that the net ionization rate, determined by averaging over the constituent GaAs and AlGaAs layers, approaches the weighted average of the constituent bulk rates at high electric field strengths. (Edited author abstract) 15 refs.

## Magnetic Field Effects

**094050 HIGH SPEED PULLING OF GaAs SINGLE CRYSTAL USING THE MAGNETIC FIELD APPLIED LEC TECHNIQUE.** The properties of high pulling rate (20-27 mm/h) LEC GaAs single crystals under a magnetic field are investigated by using the infrared absorption coefficient,  $\alpha$ , at a wavelength of 1.0  $\mu$ m, the microscopic resistivity and the Hall measurement technique. The distributions of  $\alpha$  and the microscopic resistivity in these crystals are not as homogeneous as those of the conventional 9 mm/h pulling rate crystal with or without magnetic field. After whole ingot annealing at 950°C, however, high speed pulling crystals are drastically changed to the homogeneous in the distribution of  $\alpha$  and the resistivity. This is attributed to the increase and the homogeneous distribution of the native deep donor in the crystals. (Edited author abstract) 14 refs.

**094051 MAGNETIC FIELD DEPENDENCE OF GATE VOLTAGE AND CURRENT IN A GaAs-HETEROSTRUCTURE IN THE QUANTUM HALL REGIME.** The current flow at a fixed gate voltage and the floating gate voltage for fixed charge density in a gated GaAs heterostructure have been measured as a function of the magnetic field. The voltage oscillations which reflect the behavior of the chemical potential have been resolved. The experimental results are explained by a statistical model of inhomogeneities in the carrier concentration implying an effective density of states between the Landau levels. (Edited author abstract) 14 refs.

**094052 METASTABLE SHALLOW DONOR STATES OF n-GaAs IN A MAGNETIC FIELD.** The photothermal spectrum of shallow donors in n-GaAs has been investigated at various magnetic field strengths up to 4T at different temperatures between 1.4 and 12K. Weak spectral structures observed at frequencies above the dominant  $1s \rightarrow 2p_{+1}$  line are attributed to optical excitations into metastable states which arise in a magnetic field. The final states of these transitions can be unambiguously assigned by using high field quantum numbers. (Author abstract) 10 refs.

Wagner, H.P. (Univ Regensburg, Regensburg, West Ger); Prettl, W. *Solid State Commun* v 66 n 4 Apr 1988 p 367-369.

**094053 ELECTRON-PHONON INTERACTION OF A TWO-DIMENSIONAL ELECTRON GAS IN A STRONG MAGNETIC FIELD.** The energy relaxation rate due to phonon scattering of a quasi two-dimensional electron gas is calculated for a GaAs quantum well in the presence of a strong magnetic field. Degenerate electron statistics and Gaussian broadened Landau levels are taken into account, as well as a nonequilibrium phonon distribution in case of polar optical phonon scattering. For

electron-acoustic phonon scattering it is found that the energy loss at low electron temperatures ( $kT_e < \hbar\omega_{ac}$ ) is directly proportional to the density of states at the Fermi level and is inversely proportional to well thickness. For polar optical phonon scattering magnetophonon resonances are found at high electron temperatures ( $kT_e > \hbar\omega_{ac}$ ), although the phonons are not in equilibrium with the bath. (Author abstract) 18 refs.

**094054 HOT ELECTRON TRANSPORT PARALLEL TO STRONG MAGNETIC FIELDS IN GALLIUM ARSENIDE.** Electrical conductivity of very lightly doped n-type gallium arsenide parallel to strong magnetic fields was studied in electric fields up to 1kV/cm. At 4K, conductivity is dominated by impact ionization of shallow donor levels, which are deepened by the magnetic field. Large effects of magneto-impurity resonances are observed. Measurements near liquid nitrogen temperature indicate that parallel magnetic fields induce a transition from sublinear to superlinear conductivity. (Author abstract) 24 refs.

## Magnetic Properties

**094055 OBSERVATION OF AHARONOV-BOHM MAGNETORESISTANCE OSCILLATIONS IN SELECTIVELY DOPED GaAs-AlGaAs SUBMICRON STRUCTURES.** Aharonov-Bohm magnetoresistance oscillations are investigated in a selectively doped GaAs-AlGaAs submicron ring with a width of 0.35  $\mu$ m and a diameter of 1  $\mu$ m. The ring is fabricated from a MBE grown film making use of electron beam lithography and dry etching methods. A wire with submicron width and several micron length, which is fabricated for comparison, shows only aperiodic fluctuations with an average period much larger than  $h/e$ . However, the ring shows the MR oscillations with the period of  $h/e$  due to AB effect, superimposed on aperiodic fluctuations. (Author abstract) 12 refs.

**094056 SAMPLE SIZE DEPENDENCE OF MAGNETOCONDUCTANCE FLUCTUATIONS IN NARROW n<sup>+</sup>-GaAs WIRES.** Submicron sized n<sup>+</sup>-GaAs wires are fabricated using MOCVD and electron beam lithography techniques, and effects of sample size on magnetoconductance fluctuations have been investigated. It is found that the magnitude of the fluctuation decreases by ensemble averaging with increasing sample size in wires with the width and the length larger than the inelastic scattering length. It is found that the fluctuation becomes larger than the predicted value in wires with the width narrower than the inelastic scattering length. (Author abstract) 9 refs.

Ishibashi, K. (Osaka Univ, Toyonaka, Jpn); Kawai, H.; Gamo, K.; Namba, S.; Ishida, S.; Murase, K.; Aoyagi, Y.; Kawabe, M. *Solid State Commun* v 63 n 12 Sep 1987 p 1169-1171.

## Manufacture

**094057 GALLIUM ARSENIDE - FROM MINE TO MICROCIRCUIT.** Gallium arsenide is the second most important semiconductor material for the manufacture of electronic devices. The main sources of the refined metal are in Europe - France, Germany, Switzerland and Hungary - and the Far East. There are also significant sources in North America. The only application is in the electronics industry. The annual supply of high-purity grade Ga in 1985 is estimated to have been 40-50 t (60%

to GaP, 40% to GaAs). Available resources are abundant, being tied to aluminium supply. 3 refs.

## Mathematical Models

**094058 PHYSICS FOR MODELS OF GALLIUM ARSENIDE DEVICES.** Klauder's self-energy methods (third-level and fifth-level) have been applied to calculate the effects of carrier-dopant ion interactions on parameters for modeling GaAs devices. The effects of carrier-carrier interactions have been calculated by modifications to the theory of Abram et al. The changes in the band edges and effective intrinsic carrier concentrations for both n-type and p-type GaAs are given. Significant results are that device models should include separate and distinct values for the changes in band edges and effective intrinsic carrier concentrations in n-type and p-type material and that the effects of bandgap narrowing and degeneracy are separately large but competitive. 6 refs.

**094059 MOMENTS OF THE BOLTZMANN TRANSPORT EQUATION AS APPLIED TO THE GALLIUM ARSENIDE PERMEABLE BASE TRANSISTOR.** Solutions to the first three moments of the Boltzmann transport equation and Poisson's equation are obtained for a permeable base transistor (PBT) using linearized, block implicit (LBI) and ADI techniques. Two level electron transfer is considered. The results of the simulations are compared to results obtained from the drift and diffusion equations. The comparison indicates that nonequilibrium transport and velocity overshoot are important in the PBT. The predicted I-V characteristics of the device show substantially higher current levels and a higher cutoff frequency are obtained with the moment equations. (Author abstract) 9 refs.

## Measurements

**094060 MEASUREMENT OF PHYSICAL PARAMETERS OF GaAs EPITAXIAL STRUCTURES.** The paper gives a summary of measuring methods and techniques used for characterization and quality testing of GaAs epitaxial layers in specialized laboratory of basic physical measurements of the TESLA Electronics Research Institute (TERI). Epitaxial GaAs layers grown by chloride technique are used for the manufacture of metal-semiconductor field-effect transistors (MESFETs) and microwave monolithic integrated circuits (MMICs). (Author abstract) 9 refs.

Vesely, Miroslav (TESLA Electronics Research Inst, Prague, Czech). *Tesla Electron* v 18 n 3 Sep 1985 p 88-93.

**094061 INFLUENCE OF IN SUBSTITUTION AND PLASTIC DEFORMATION ON AS<sub>Ga</sub>-RELATED PHOTOLUMINESCENCE IN GaAs.** Low-temperature photoluminescence experiments have been carried out on semi-insulating GaAs crystals undoped or containing approximately  $5 \times 10^{19}$  In atoms cm<sup>-3</sup>. A broad band peaking around 0.8 eV is observed which is generally related to the antisite defect As<sub>Ga</sub>. The effect of In substitution or plastic deformation is to shift this band towards higher energies by 10-25 meV. This positive energy shift is quantitatively accounted for by considering the stress fields induced by the incorporation of indium or the creation of dislocations. (Author abstract) 22 refs.

A.; Svob, L.; Marfaing, Y. *Phil Mag Lett* v 55 n 5 May 1987 p 239-245.

**094062 Ge DIFFUSION INTO GaAs BY PULSED LASER IRRADIATION.** Ge diffusion into GaAs from thin evaporated layers as sources is reported. Irradiation with a Q-switched ruby laser gives rise to n-type diffused layers of a thickness from 240 to 710 Angstrom. A strong compensation of the diffused layers, that cannot be removed by thermal annealing, was observed. From the present experimental results it can be inferred that the diffusion coefficient increases at the melting point by 5 to 6 orders of magnitude. (Author abstract). 24 refs.

**094063 CONVERGENT-BEAM ELECTRON DIFFRACTION FROM AlGaAs/ GaAs SINGLE QUANTUM WELLS.** Relative spectroscopic measurements of the bulk modulus of GaInAsP lattice-matched to InP yield a value within 1 percent of that of InP. This surprising result is not in agreement with accepted interpolated values but is predicted by Keyes' empirical scaling rule for elastic constants. (Author abstract). 9 refs.

Cherns, D. (Univ of Bristol, Bristol, Engl). *Philos Mag Lett* v 58 n 1 Jul 1988 p 45-51.

## Melting

**094064 BEAM-INDUCED COMPOSITION CHANGES IN 'MELTED' GaAs.** Analytical electron microscopy has been used to study the melting behavior of GaAs crystal under strong illumination with an electron beam. It is found that the chemical composition has been changed to Ga:As=2:1 after being melted. The decrease of As atoms is interpreted as being due to evaporation of As into the vacuum. (Edited author abstract) 7 refs.

## Metallizing

**094065 HIGH-TEMPERATURE METALLISATION SYSTEMS FOR TRANSIENT ANNEALING OF GaAs.** The letter reports the results of rapid thermal annealing of W, Ta and TaSi<sub>x</sub> on GaAs. The results indicate that rapid thermal annealing results in contact stability to higher temperatures than is seen in conventional annealing. The stability of tantalum is greatly improved when silicon is added to the system, forming a TaSi<sub>x</sub> contact. The preliminary results of TaSi<sub>x</sub> on In-doped GaAs indicate that the process of Ga and/or As outdiffusion is inhibited up to a temperature of 1050°C. (Edited author abstract) 4 refs.

**094066 INFLUENCE OF GALLIUM IN A METALLISATION ON GaAs.** ESCA analysis of systems composed of Ge, Ga, Au layers alloyed to GaAs is reported to elucidate the influence of gallium in a metallization scheme. The results reveal that a metal system containing gallium shows an absence of arsenic in the alloyed surface, and thus its presence precludes an early dissociation of GaAs. The metallurgical analyses are correlated to previously reported unstable performance of GaAs/Au contacts and thermally stable electrical behavior of GaAs/Au/Ga Schottky diodes. (Author abstract) 13 refs.

**Microscopic Examination** See Also SEMICONDUCTING ALUMINUM COMPOUNDS—Microscopic Examination.

**094067 HIGH RESOLUTION ELECTRON MICROSCOPY AND ETCHING STUDY OF TWINS IN GaAs.** The combination of etching, photoetching, electron diffraction and high resolution electron microscopy technique was used to characterize twins in GaAs. These techniques were applied to study (001) oriented samples taken from Si-doped n-type horizontal Bridgman GaAs crystals containing twins. From photoetching and etching it is concluded that the intersection of the twin plane with the (001) plane is parallel to [11 $\bar{1}$ ] type. Selected area electron diffraction and high resolution electron microscopy (HREM) on chemically thinned samples, performed on matrix and twin areas, showed the twin to be a 180° rotation or a reflection twin with a (111) composition plane. The model is further confirmed by image calculations. HREM observations reveal the presence of a thin surface contamination layer of unknown composition on the twin portion of the sample. However this layer did not influence the high resolution images of the GaAs. (Edited author abstract) 18 refs.

**094068 LATTICE IMAGING STUDY OF IN-DEPTH DISORDERING OF SI-IMPLANTED GaAs.** Cross-sectional high resolution transmission electron microscopy has been used to obtain direct information on the in-depth radiation damage distribution of weakly damaged GaAs by Si-ion implantation. A comparison is made between the experimental data and the calculated (using TRIM computer simulations) deposited energy by nuclear stopping for the same conditions. In particular a diffusion zone, with 200-300 Angstrom width, of high point defect concentration beyond the damage peak is detected. These point defects are interpreted as As interstitials. By direct observation, information concerning the damage- and radiation-enhanced diffusion in implanted III-V compound semiconductors is obtained. (Author abstract). 30 refs.

**094069 INVESTIGATIONS OF THE MICROHETEROGENEITY OF THE PARAMETERS OF LOCAL CENTERS IN HIGH RESISTANCE SEMICONDUCTOR MATERIALS USING SCANNING ELECTRON MICROSCOPY.** The problem of uniformity of the properties of high resistance and semiconductor materials has acquired special meaning in recent years with respect to creation of instruments with a high degree of integration. Until recently analysis of the parameters of local centers in a high resistance semiconductor has been a very complex problem, not to mention analysis of the uniformity of their distribution. The potential of a new local method for studying the parameters of local center using scanning electron microscopy (SEM), which is based on a method of photoelectric relaxation spectroscopy (PERS), is shown in this work in an example of investigation of semiinsulated gallium arsenide. 2 refs.

## Microstructure

**094070 STRAIN MODEL FOR EL2 IN GaAs.** A strain model is proposed for the mechanism of formation of EL2 in GaAs and its dependence on dislocations. This model is similar to the stress model suggested by Holmes et al. but differences exist between these two models. By using the strain model, the formation of EL2 in In-doped, dislocation-free, SI LEC GaAs can be explained. (Edited

author abstract) 11 refs. In Chinese.

Zou Yuan-xi (Acad Sinica, Shanghai, China). *Xi You Jin Shu* v 5 n 4 Nov 1986 p 241-243.

**094071 ORIGIN OF MICROTWINNING IN ROOM TEMPERATURE INDENTED UNDOPED AND n-DOPED GaAs CRYSTALS.** The origin of microtwinning in room temperature indented GaAs crystals is analyzed. It is shown that microtwinning does not take place because of the non-centrosymmetry of the crystal structure but because the friction forces acting on the 30° partial dislocations are higher than those acting on the 90° partial dislocations:  $R_{30(g)} > R_{30(a)} > R_{90}$ . A new local method for studying the parameters of local center using scanning electron microscopy (SEM), which is based on a method of photoelectric relaxation spectroscopy (PERS), is shown in this work in an example of investigation of semiinsulated gallium arsenide. (Author abstract) 28 Refs.

## Morphology

**094072 MORPHOLOGY OF GaAs AND InP (001) SUBSTRATES AFTER DIFFERENT PREPARATION PROCEDURES PRIOR TO EPITAXIAL GROWTH.** The morphology of (001) GaAs and (001) InP substrates after different preparation procedures prior to epitaxy has been studied. The effect of two commonly used polishing solutions were tested:  $\text{Br}_2\text{-CH}_3\text{OH}$  and  $\text{H}_2\text{SO}_4\text{:H}_2\text{O}_2\text{:H}_2\text{O}$ . These solutions remove a certain amount of material, but we have shown in previous papers that a residual oxide layer remains on the surface, resulting from preparation in air, which must be removed prior to epitaxial growth. The morphology of the surfaces after the above mentioned etchants and additional wet chemical deoxidation treatments was characterized using a phase contrast microscope equipped with a Nomarski interferometer. (Edited author abstract) 26 refs.

**094073 EXCITON BINDING ENERGY IN SMALL-PERIOD GaAs/Ga<sub>(1-x)Al<sub>x</sub>As</sub> SUPERLATTICES.** We report the optical determination of exciton binding energies in small-period GaAs/Ga<sub>0.7</sub>Al<sub>0.3</sub>As superlattices by means of low-temperature photoluminescence excitation spectroscopy and photoluminescence spectroscopy as a function of temperature. The heavy-hole exciton binding energy decreases with decreasing superlattice period. Our experimental findings are in reasonable agreement with a variational calculation. (Author abstract) 16 refs.

Chomette, A. (CNET, Lannion, Fr); Lambert, B.; Devaud, B.; Clerot, F.; Regreny, A.; Bastard, G. *Europhys Lett* v 4 n 4 Aug 15 1987 p 461-466.

**094074 TRANSIENT CHARACTERISTICS OF LUMINESCENCE FROM GaAs/Ga<sub>0.6</sub>Al<sub>0.4</sub>As MULTI-QUANTUM-WELL STRUCTURE UNDER RESONANT EXCITATION.** The transient characteristics of photoluminescence from the exciton band in a multi-quantum well have been examined under a resonant excitation condition of the exciton by using a time-correlated single-photon counting method. We have found that the delay, rise and decay times of the luminescence depend on wavelength of excitation and observation, and that the

dependencies disappear with increasing temperature from 20 to 50 K. These results could be well explained in terms of exciton relaxation through localized levels created by a fluctuation of the width of the multi-quantum well. (Author abstract) 5 refs.

Miyoshi, Tadaki (Yamaguchi Univ, Ube, Jpn); Aoyagi, Yoshinobu; Segawa, Yusaburo; Namba, Susumu. *Jpn J Appl Phys Part 1* v 26 n 9 Sep 1987 p 1438-1441.

**094075 EFFECTS OF AN ELECTRIC FIELD ON THE DECAY TIME OF LUMINESCENCE FROM A GaAs/Ga<sub>0.6</sub>Al<sub>0.4</sub>As MULTI-QUANTUM-WELL STRUCTURE.** The decay time of luminescence from a multi-quantum well has been measured at 20 K by using a cw mode-locked Kr laser and a synchroscan-streak camera. The decay time was found to increase with applied electric field. The increase is considered to be attributable to a field-induced carrier separation. The decay time depends on the observed wavelength of luminescence. This dependence changes with the electric field, suggesting that the energy-decreasing rate of excitons becomes slower in the presence of an electric field. (Author abstract) 10 refs.

Miyoshi, Tadaki (Yamaguchi Univ, Ube, Jpn); Aoyagi, Yoshinobu; Segawa, Yusaburo; Namba, Susumu; Sano, Naokatsu. *Jpn J Appl Phys Part 1* v 26 n 9 Sep 1987 p 1442-1446.

**094076 ELECTROLUMINESCENCE FROM A SHORT ASYMMETRIC GaAs/AlAs SUPERLATTICE.** The electroluminescence obtained from a GaAs p-n junction containing a short asymmetric GaAs/AlAs superlattice has been studied. In addition to the electroluminescence from the bulk GaAs, three more electroluminescence peaks are observed. These are due to the  $n=1$  electron-light hole states in the three narrowest wells. The electron confinement is found to be consistent with that of the  $\Gamma(\text{GaAs})$  to  $X(\text{AlAs})$  potential. (Author abstract) 11 refs.

Phillips, R.T. (Univ of Exeter, Exeter, Engl); Couch, N.R.; Kelly, M.J. *Semicond Sci Technol* v 2 n 12 Dec 1987 p 828-831.

**094077 OPTICAL PROPERTIES AND BAND STRUCTURE OF SHORT-PERIOD GaAs/AlAs SUPERLATTICES.** We have studied six GaAs/AlAs superlattices with periods ranging from 18 to 60 Å and different average aluminum composition. Three of these samples are shown to be direct bandgap materials whose band structure differs strongly from that of the corresponding alloy, but is correctly described by an envelope function calculation. The three remaining samples are shown to be indirect both in real and reciprocal space. Analysis of the time decay of the luminescence shows that this is a momentum-forbidden exciton mode allowed by disorder scattering, which leads to a luminescence efficiency comparable to that of the direct bandgap samples. Partial lifting of the degeneracy of the three X orbitals by the superlattice potential is also observed. Finally, we take advantage of the strong dependence of these indirect transition energies on the band discontinuities to estimate the valence band offset to be about 550 meV in this system. (Edited author abstract) 35 refs.

**094078 OBSERVATION OF RESOLVED 2s EXCITON LINES IN (AlGa)As/GaAs QUANTUM WELL.** All the major electronic companies are investing heavily in gallium arsenide (GaAs) technology with a view to its commercial exploitation in the optic and electro-optic fields. Several articles have cataloged its possible uses, when combined with the mixed crystal aluminum gallium arsenide ((AlGa)As), in layered structures of atomic dimensions. Many technological and physical questions remained unanswered, in particular, one problem concerned with the binding energy of electron-hole pairs in quantum wells. The uncertainty arose from experimental

results which conflicted with each other by a factor of nearly two and it was left to calculation to attempt to resolve the difficulty. In this article we show how a study of the details of the photoluminescence from GaAs/(AlGa)As multiple quantum wells and the correct interpretation of the results has led to an unequivocal determination of this quantity. 6 refs.

**094081 AlAs PHONON PARAMETERS AND HETEROSTRUCTURE CHARACTERIZATION.** Infrared and Raman spectra from an AlAs-GaAs heterostructure yield phonon parameters for non-oxidized pure AlAs at 300, 77 and 6 K, which have not been thoroughly established. Strong infrared interference effects in the heterostructure are identified and produce a large peak near the GaAs LO frequency. This explains an anomalous double peak previously observed in the infrared spectroscopy of  $\text{Al}_x\text{Ga}_{1-x}\text{As}$ -GaAs heterostructures. (Author abstract) 12 refs.

Perkowitz, S. (Emory Univ, Atlanta, GA, USA); Sudharasan, R.; Yom, S.S.; Drummond, T.J. *Solid State Commun* v 62 n 9 Jun 1987 p 645-647.

**094082 LIGHT SCATTERING IN GaAs PARABOLIC QUANTUM WELLS.** We report the observation of electronic light scattering in photoexcited parabolic GaAs- $\text{Al}_x\text{Ga}_{1-x}\text{As}$  quantum wells. The spectra show sharp peaks corresponding to transitions between sublevels in the conduction band. The precision of the measurements allows a test of the simple harmonic oscillator model for the energy level structure. The energy gap and alloy composition of the  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  layers are determined from resonance Raman scattering by optical phonons. We use these results to calculate the conduction band offset  $Q_c$ . We obtain  $Q_c$  approx. 0.7, in agreement with recent experiments in square quantum wells. (Author abstract) 12 refs.

**094083 PHOTOQUENCHING AND RECOVERY EFFECTS OF EL2 ABSORPTION IN GaAs.** Optical absorption spectroscopy on the major midgap donor (EL2) in GaAs shows that the metastable state of the EL2 level ( $\text{EL2}^*$ ) can be optically recovered to the normal state ( $\text{EL2}^0$ ) at 11 K. On the basis of the transient properties of the photoquenching and recovery effects, we suggest

that these effects occur as a result of a dynamic balance between the  $EL2^0 \rightarrow EL2^*$  and  $EL2^* \rightarrow EL2^0$  transitions. (Author abstract) 10 refs.

**094084 PHOTO-HALL STUDY OF THE OPTICALLY ENHANCED PHOTOCURRENT IN SEMI-INSULATING LEC GaAs.** The photocurrent of semi-insulating GaAs is enhanced by long time excitation with photons of energy higher than 1 eV. Photo-hall experiments on the enhanced photocurrent reveal that this is mainly due to holes, and that the mobility is increased in conditions of strong photocurrent enhancement. This is discussed on the basis of metastability of midgap levels in GaAs. Thermal annealing experiments showed that likely EL6 is involved in this phenomenon. (Author abstract) 14 refs.

**094085 OBSERVATION OF 1.13 (EV% POLARIZED) LUMINESCENCE BAND IN PLASTICALLY DEFORMED GaAs.** A luminescence band centered at 1.13 eV, with a width of 140 meV at 77 K, has been observed in GaAs after plastic deformation at 400°C by uniaxial compression. This band is polarized normally to the primary glide plane, which suggests that it comes from dislocations rather than from point defects. A configuration coordinate diagram for this dislocation level is proposed. (Edited author abstract) 11 refs.

**094086 MEASUREMENTS OF ABOVE-BANDGAP OPTICAL ANISOTROPIES IN THE (0 0 1) SURFACE OF GaAs.** We report on a detailed experimental study of above-bandgap optical anisotropies of the (0 0 1) surface of GaAs as a function of doping concentration and conductivity type. We conclude that the measured spectra have two components, a first one which depends on these two parameters and a second one which is independent of them. The first component is actually dependent on the surface electric field due to the pinning of the Fermi level at the sample surface states. (Author abstract) 7 refs.

**094087 IMAGE ANALYSIS OF EL2 DISTRIBUTIONS IN LEC GaAs SI MATERIALS.** In a recent paper we showed that EL2 centers are not especially concentrated on dislocations as is the usual stated opinion. Photoquenching experiments and the analysis of infrared transmission images enable the identification of the local EL2<sup>+</sup> contribution in the cell pattern; a profile of the calculated EL2<sup>+</sup> quenched center densities was deduced showing a lower density in the walls and a higher density in an intermediate zone surrounding the inner cell. In this letter we propose a confirmation of this schematic distribution by extending the calculation to the complete image. A quantitative image of the EL2<sup>+</sup> densities is presented. A discussion is introduced which compares this new point of view with previous results reported in the literature, especially the conclusions on infrared luminescence images. (Author abstract) 14 refs.

**094089 DEEP LEVEL CHARACTERIZATION IN SEMI-INSULATING LEC GALLIUM ARSENIDE.** The temperature dependent Hall effect, photoconductivity, IR absorption, and C - U analysis are applied for characterizing semi-insulating undoped LEC gallium arsenide samples. It is shown that a combination of the different experimental techniques can give a satisfactory description of the physical properties of this material. In particular it is found that EL2 is the dominant deep level, although in particular cases the photoconductivity threshold can be lower than 0.7 eV. The activation energy from Hall effect measurements can be as low as 0.42 eV. (Author abstract) 20 refs.

**094091 LIGHT ABSORPTION AND HYPER-RAMAN SCATTERING BY MANY-ELECTRON COMPLEXES IN QUANTUM WELL STRUCTURES.** In the absorption and luminescence spectra of GaAs/Al<sub>x</sub>Ga<sub>1-x</sub>As transitions to light-hole exciton and heavy-hole exciton states are detected. Also a broad luminescence band is ascribed to biexciton luminescence. However, more reliable methods of biexciton detection are two-photon absorption and hyper-Raman scattering. The authors report on estimations of the bihole dissociation energy and oscillator strengths due to bihole light absorption, the probability of intersubband optical transitions of heavy holes, the probability of bihole dissociation accompanied by LO phonon emission, the probability of two-photon Raman scattering with the participation of the biexciton, consisting of two electrons and two heavy holes. 11 refs.

**094092 TRIPLY RESONANT SECOND-ORDER RAMAN SCATTERING IN GaAs.** We have achieved conditions for triply resonant second-order Raman scattering induced by the iterated electron - one-phonon interaction by applying uniaxial stress on bulk GaAs and thus producing an energy splitting between the light- and heavy-hole valence bands equal to the energy of two scattering phonons. We show that all three energies involved in this process, the incident and the outgoing photon energy, and also the intermediate energy, are simultaneously in resonance with an electronic transition. Under such conditions we observe, even for crossed polarizations, scattering intensities much larger than the ones seen in resonant 2LO-phonon Froehlich intraband Raman scattering for unstressed samples. **094096 ON THE ORIGIN OF CATHODOLUMINESCENCE CONTRAST PHENOMENA IN SEMI-INSULATING GaAs.** The microscopic origin of homogenization can be investigated by cathodoluminescence (CL) measurements on a micrometer scale. CL micrographs of as-grown and of annealed s.i.-GaAs show cellular structures with bright cell walls and dark cell interiors. CL micrographs of annealed material show additional island-like structures in the cell interiors which seem to be the microscopic origin for the homogenization. The observed CL properties can be explained in terms of a non-radiative recombination process which is coupled to gallium vacancies or to the intrinsic EL2 defect. Annealing of GaAs leads to an increase of the EL2 concentration. (Edited author abstract). 18 Refs.

**094097 ELLIPSOMETRIC STUDIES OF NATURAL FILMS ON GaAs.** Ellipsometric angles  $\Delta$  and  $\psi$  of about 20 samples of GaAs single-crystals with natural thin films were studied for several angles of incidence at room temperature within a several years period at  $\lambda = 632.8$  nm.  $\Delta$  and  $\psi$  are used to determine the optical constants  $n$  and  $k$  and the thickness and refractive index of thin surface film. Also studied were the changes of  $\Delta$  and  $\psi$  with temperature during several consecutive heating-cooling cycles for two samples in the range from 20 to 201°C. The experimental results are interpreted in terms of the temperature coefficients  $dn/dT$  and  $dk/dT$  and desorption and adsorption of gases and vapours from and on the sample surface. (Author abstract). 20 Refs.

**094100 THEORY OF TRANSIENT ENERGY TRANSFER IN GALLIUM ARSENIDE.** Numerical calculations are given for optical two-beam coupling in undoped, semi-insulating GaAs using picosecond pulses. Absorption at the intrinsic defect EL2, two-photon absorption, free-carrier absorption, photorefractive gratings, free-carrier gratings, and absorption gratings are included. Results for normalized probe transmission as a function of pump fluence and as a function of pump-probe delay show that the major effects are energy transfer from pump to probe or from probe to pump (depending on crystal orientation) due to the photorefractive effect, two-photon absorption, and free-carrier transient energy transfer from the pump to the probe. 25 refs.

Valley, George C. (Hughes Research Lab, Malibu, CA, USA); Smirl, Arthur L. *IEEE J Quantum Electron* v 24 n 2 Feb 1988 p 304-310.

**094101 STUDY OF THE OPTICAL PROPERTIES OF SEMICONDUCTORS WITH SYNCHROTRON RADIATION FROM THE VEPP-2M STORAGE RING.** This paper reports on evaluation of measurements of reflectivity on III-V semiconductors GaAs for a broad spectral range. The measurements were made using both a classical source (from 4 to 13 eV) and synchrotron radiation from the VEPP-2M storage ring (from 14 to 26 eV). The method of evaluation is based on a fit of the relative reflectivities as obtained from Fresnel formulas to the measured data for 10 discrete angles of incidence. In the range from 19 to 26 eV, where the optical transitions from atomic 3d-states of Ga to the conduction band of the GaAs are predominant, the experimental results were compared with pseudopotential calculations. A good qualitative agreement with the experimental data was found. (Author abstract) 19 refs.

**094102 THEORETICAL STUDIES OF POLARIZATION DEPENDENT ELECTRO-OPTICAL MODULATION IN LATTICE MATCHED AND STRAINED MULTI-QUANTUM WELL STRUCTURES.** We report on polarization-dependent optical absorption for excitonic and interband transitions in lattice matched (GaAs/AlGaAs) and strained (biaxial tensile strain - GaAsP/AlGaAs; biaxial compressive strain - InGaAs/AlGaAs) multi-quantum-well structures

in the presence of transverse electric fields. The hole states are solved by using the Kohn-Luttinger Hamiltonian and using an eigenvalue technique. The effect of heavy-hole and light-hole mixing due to the strain, electric field and quantization is studied. Under biaxial tensile strain the heavy-hole and light-hole transition can coincide, leading to interesting polarization dependent effects. Results are presented for excitonic and interband transitions. (Author abstract) 21 refs.

**094103 ABSORPTION AND PHOTOLUMINESCENCE STUDIES OF THE TEMPERATURE DEPENDENCE OF EXCITON LIFE TIME IN LATTICE-MATCHED AND STRAINED QUANTUM WELL SYSTEMS.** We present systematic studies of the temperature dependence of linewidths and lifetimes of excitonic transitions in quantum wells grown by molecular beam epitaxy using both photoluminescence (PL) and optical absorption. The temperature ranged from 6K to room temperature. Samples under investigation were lattice-matched GaAs/AlGaAs and InGaAs/InAlAs, and strained InGaAs/GaAs and InGaAs/AlGaAs quantum well systems. In addition, the effects of well-size variations in GaAs/AlGaAs quantum wells were measured and analyzed. In all cases we were able to observe the excitonic transitions up to room temperature. The exciton lifetimes were calculated as a function of temperature using the Heisenberg uncertainty principle. We found the lifetime decreases significantly with temperature and increases with increasing well size. These results are interpreted in terms of the exciton-phonon interaction and are expected to be very useful for the design of semiconductor optical devices. (Edited author abstract) 24 refs.

**094104 NONLINEAR OPTICS BELOW THE BANDEDGE IN GaAs QUANTUM WELL HETEROSTRUCTURES.** Most studies of the optical properties of GaAs/AlGaAs quantum wells have focussed on the wavelength region above the bandedge, where there exists a rich spectrum of sharp quasi-two-dimensional excitons. Much less attention has been paid to quantum well properties at incident photon energies less than the ground state exciton transition. This below-gap spectral region is of importance for several reasons. Recent experiments in GaAs quantum wells have revealed strong electro-optic and all-optical excitonic effects for light propagating in the transparent wavelength range of the crystal. 5 refs.

## Order-Disorder

**094109 PAIRED TEMPERATURE SPECTROSCOPY (PATS) FOR GAP STATES IN ORDERED AND DISORDERED SEMICONDUCTORS: II. EXPERIMENTAL APPLICATIONS.** We present applications of paired temperature spectroscopy (PATS) to deep levels in liquid encapsulated Czochralski (LEC) grown and irradiated GaAs and InP. In GaAs, the level is near the midgap and appears to belong to the EL2 family of defects. In InP, we find two levels: one at 0.34 eV and the other at 0.42 eV. We have also carried out deep level transient spectroscopy (DLTS) on these levels. The agreement between PATS and DLTS is good. Our exercise establishes PATS as a successful near-isothermal technique for characterizing traps in semiconductors. (Author abstract) 5 refs.

## Oxidation

**094112 HIGH-PRESSURE THERMAL OXIDATION OF GALLIUM ARSENIDE AT 250°C.** It is shown that the native oxide of GaAs can be thermally grown easily at a temperature of 250°C using a high-pressure oxidation technique. The resulting oxide films are uniform, chemically stable and have a breakdown strength of  $6.8 \times 10^6$  v/cm and a bandgap energy greater than 6.5 eV. The chemical composition of the oxide films is studied using X-ray photoelectron spectroscopy, and it is found to contain oxides of both gallium and arsenic. (Author abstract) 9 refs.

Bhat, K.N. (Indian Inst of Technology, Madras, India); Basu, N. *Electron Lett* v 23 n 24 Nov 19 1987 p 1329-1330.

**094113 ARSENIC GROWTH ON THE GALLIUM ARSENIDE SURFACE DURING OXIDATION.** Crystalline arsenic was observed to grow on the surface of GaAs during exposure to continuous-wave laser radiation. A study of the time development of the arsenic growth as revealed by Raman backscattering indicated that a surface diffusion process was responsible for limiting the growth process. Temperature measurements were performed from which the diffusion barrier energies were obtained for various GaAs samples. From these results the diffusion process was shown to depend on the Fermi level of the sample. (Author abstract) 10 refs.

## Performance

**094116 DEVELOPING THE NEXT GENERATION OF INTEGRATED CIRCUITS.** For more than two decades, the telecommunications industry has exploited the properties of silicon to produce increasingly faster, more powerful integrated circuits (ICs). Now these silicon chips - capable of shuttling electrons at high speeds across tightly populated chip surfaces - are being joined by a new, significantly faster generation of ICs, fabricated in gallium arsenide. An aggressive research and development program, is resulting in the design, fabrication, and testing of experimental gallium arsenide (GaAs) chips. In developing these experimental chips, BNR is exploiting the high-speed, low-power, and light-emitting properties of GaAs.

Jay, Paul; Streater, Rick. *Telesis* v 14 n 1 1987 p 4-13.

**094117 GALLIUM ARSENIDE DIGITAL TECHNOLOGY.** The features of GaAs digital technology are pointed out. Potential applications in electronic warfare, communications, electronic countermeasures, and radar are proliferating as people become aware of the capabilities of digital devices in this high-speed low-power high-temperature-tolerant material. New horizons in packing density, functional complexity, and system integration are opening up.

Smith, Irl W. *Electron Prog* v 28 n 3 1987 p 11-22.

**094118 GALLIUM ARSENIDE ON SILICON: A REVIEW.** Recent advances in the performance of electronic and optical devices fabricated in GaAs on Si substrates have led to the consideration of this hybrid technology for novel applications. These range from simply replacing GaAs substrates with large area, light weight, high strength Si substrates to highly desirable integration of GaAs and Si devices and circuits on the same chip. Other applications include the use of GaAs as an interlayer for subsequent growth of long wavelength compound semiconductors (III-V and II-VI) for focal plane arrays with built-in Si signal processors. (Author abstract) 42 refs.

Morkoc, H. (Univ of Illinois at Urbana-Champaign, Urbana, IL, USA); Unlu, H.; Zabel, H.; Otsuka, N. *Solid State Technol* v 31 n 3 Mar 1988 p 71-76.

**094119 SUBNANOSECOND SILICON ECL GATE ARRAYS FACE CHALLENGE FROM GaAs AND CMOS.** The mainstay of the fastest digital systems, silicon ECL gate arrays face competition from high-density CMOS, bipolar-CMOS, and gallium arsenide. It is pointed out that due to recent advances ECL's picosecond delays and gate complexity ensure its lead.

Bursky, Dave. *Electron Des* v 35 n 13 Jun 12 1986 p 74-80, 82, 84.

**094120 FASTER AND SMALLER WITH GALLIUM ARSENIDE.** The advantages of using gallium arsenide as semiconductor material over silicon are pointed out. Its most notable characteristic is that its electrons can be made to travel at speeds 5 times faster in GaAs than in silicon. This is specially significant wherever fast electronic switches are needed as in microwave and optical communications. GaAs can also be made to emit light and can be used to manufacture optical elements such as lasers and optical detectors. However, GaAs is a more difficult material to work with than silicon and its technology is less mature. Also, it is more expensive. It is unlikely to supplant silicon as the general semiconducting material and it is an alternative to silicon in some specialized applications such as telecommunications and optoelectronics.

Grad, Paul. *J Inst Eng Aust* v 60 n 17 Aug 19 1988 p 16-18.

**Photoconductivity** See Also OPTICAL GRATINGS.

**094121 VANADIUM IN GaAs: FOR A REVISION OF THE ENERGY LEVEL SCHEME.** Photoconductivity measurements performed at 4.2K on semi-insulating

V-doped GaAs, give support to identify the isolated vanadium ( $V_{Ga}$ ) as a double acceptor in gallium-arsenide. This behavior would explain all the known properties of the V-doped crystals including the semi-insulating character. The first transition would be at  $E_c - 0.65 \pm 0.03$  eV and the second at  $E_c - 0.16 \pm 0.01$  eV. (Author abstract) 14 refs.

Barrau, J. (CNRS, Toulouse, Fr); Sorba, A.; Brousseau, B.; Brousseau, M.; Leotin, J.; Binh, Phi Hoa; Reclus, G. *Solid State Commun* v 62 n 11 Jun 1987 p 753-755.

**094122 QUENCHING PHENOMENON OF PHOTOCONDUCTANCE IN INDIUM DOPED DISLOCATION FREE GaAs.** In photoconductance measurements on indium doped semi-insulating GaAs, we have found that the quenching phenomenon of photoconductance is enhanced with the reduction in the dislocation density due to the addition of a few percent indium atoms to GaAs. We propose that the enhancement in the quenching phenomenon associates with increasing the internal stress due to the decrease in dislocation density. The time dependence of photoconductance also suggests the existence of the state or the path assisting the transition from normal EL2 states to those metastable states in indium doped GaAs. (Author abstract) 18 Refs.

**094123 EL2 IN PHOTOCONDUCTIVITY SPECTRA OF Cr-DOPED SI GaAs BULK CRYSTALS.** Extrinsic photoconductivity measurements at 70 and 293 K in Cr-doped Si GaAs bulk crystals have been carried out in order to characterize the deep levels in this material. The photoconductivity spectra reveal two characteristic structures extended in the low-energy and the high-energy regions, respectively. It is shown that low-energy structure is connected with the  $Cr^{2+}$  deep acceptor level and the high-energy one with the EL2 deep donor level. The spectrum measured after an intentionally photo-induced transfer of EL2 into its metastable state confirms our interpretation of the origin of the high-energy structure. We believe that our study is the first to identify the EL2 contribution to the photoconductivity spectra of Cr-doped Si GaAs. The optical ionization energy with respect to the conduction band and the Frank-Condon parameter of  $Cr^{2+}$  centers are obtained from the experimental results. (Author abstract) 25 refs.

## Physical Properties

**094125 PHOTOINDUCED RECHARGING PHENOMENA AND VANADIUM-RELATED CENTRES IN GaAs:V.** Photoinduced recharging phenomena are studied at low temperatures ( $T < 80$  K) on n-type and semi-insulating GaAs:V by optical absorption, C-EPR, and TD-EPR. Illumination with  $h\nu_{exc} > 1.05$  eV into the photoionization absorption  $\alpha_{II}$  excites electrons into the conduction band and recharging takes place, which has been monitored by optical absorption and EPR. The center responsible for  $\alpha_{II}$  appears to be a V-containing complex of unknown structure, rechargeable under illumination from (V-X) into (V-X)<sup>+</sup>. The  $V^{2+}/(II)$  center measured by TD-EPR is shown to be a second V-containing

ing complex different from (V-X). The interpretation of all experiments does not require a V-related mid-gap level. (Edited author abstract) 20 refs.

**094126 EFFECT OF SEMICONDUCTOR PARAMETERS ON SPECTRAL SENSITIVITY OF A GALLIUM ARSENIDE-ELECTROLYTE CONTACT.** The dependence of spectral sensitivity of a gallium arsenide contact with a 0.01 N KCl solution in dimethylformamide upon impurity concentration in the semiconductor and applied anode bias is studied. It is known that a decrease in dopant level increases spectra sensitivity in the long-wave region. Experimental results are compared with calculation and are found to agree satisfactorily. The results are relevant to solar cells. (Edited author abstract) 13 refs.

**094127 INFLUENCE OF MANY-BODY EFFECTS ON THE CYCLOTRON RESONANCE MASS OF TWO-DIMENSIONAL POLARONS WITH APPLICATION TO GaAs-Al<sub>1-x</sub>Ga<sub>x</sub>As% HETEROSTRUCTURES.** The influence of many-body effects on the cyclotron resonance mass of two-dimensional polarons is investigated. Firstly, the occupation effect is considered, which arises from the Fermi-Dirac statistics. It is found that (1) the occupation effect reduces the polaron effect, i.e. the cyclotron resonance mass renormalization due to the polaron effect is reduced over the whole magnetic field region, (2) for a fixed electron density the cyclotron resonance mass shows an oscillating behavior as a function of the magnetic field. Secondly, the effect of static screening on the polaron cyclotron resonance mass is examined. The electron screening is found to reduce further the cyclotron resonance mass renormalization. After taking into account the nonparabolicity of the electron energy band, the calculated cyclotron resonance mass is compared to the recent experimental data for GaAs-Al<sub>1-x</sub>Ga<sub>x</sub>As heterostructures. Good agreement is found for magnetic fields  $H > 12$  T. (Edited author abstract) 26 refs.

**094129 THEORY OF THE SPECTRAL ACOUSTIC PHONON EMISSION INTENSITY OF HOT 2D ELECTRONS IN QUANTIZED n-INVERSION LAYERS.** The spectral acoustic phonon emission intensity of the hot quasi-two-dimensional electron gas (2DEG) in quantized n-Si(GaAs) inversion layers is calculated as a function of the phonon angular frequency  $\omega$  at different values of the carrier temperature  $T_c$  and density  $N_s$ . In the

long wave length limit ( $\hbar\omega \ll k_B T_c$ ) the emission intensity increases  $\propto \omega^s(\omega^s+1)$  for bulk- (surface-) modes where  $s=3$  for the unscreened acoustic deformation potential coupling. At  $\omega \approx v_j 2k_F$  ( $v_j$ : sound velocity of the phonon mode  $j$ ,  $k_F$ : radius of the Fermi-circle) the emission intensity reaches a maximum whose position is shifted to higher  $\omega$ -values if  $N_s$  increases. For given values of  $N_s$ ,  $T_c$  (lattice temperature) and  $\theta$  (emission angle) the emission intensity maximum of the n-GaAs inversion layer is found to be about one order of magnitude smaller than the intensity maximum of the n-Si inversion layer. (Author abstract) 14 refs.

**094130 NON-PARABOLICITY AND ANISOTROPY IN THE CONDUCTION BAND OF GaAs.** The spin-doublet splitting and effective-mass shift of the cyclotron resonance in n-GaAs has been studied in high static magnetic fields applied along the (001), (011) and (111) crystal directions. A clear anisotropy of the conduction band has been observed in the orientation dependence of the spin-doublet splitting. Experimental results are described using a five-level k-p model. Comparison between the experimental data and this theoretical model allowed the determination of important band-structure parameters for GaAs, such as the interband momentum matrix element. (Author abstract) 18 refs.

**094131 HOT PHOTOLUMINESCENCE SPECTROSCOPY INVESTIGATIONS OF L-VALLEY SPLITTING AND INTERVALLEY SCATTERING IN UNIAXIALLY STRESSED GALLIUM ARSENIDE.** Hot photoluminescence spectra (HPL) of uniaxially stressed GaAs are investigated. From the stress-induced shift and splitting in the HPL spectra, shear deformation potentials for the subsidiary minima have been determined with a good accuracy. From the stress dependence of the relative intensities in the split spectrum a value of the coupling constant for scattering between the L-valleys is obtained as  $D_{LL} = (5 \pm 1) \times 10^8$  eV cm<sup>-1</sup>. (Edited author abstract) 13 refs.

**094134 HEATING OF COLD ELECTRONS BY A WARM GaAs LATTICE: A NOVEL PROBE TO CARRIER-PHONON INTERACTION.** The polar optical scattering of electrons and holes is studied by

picosecond luminescence in a GaAs/Al<sub>x</sub>Ga<sub>1-x</sub>As heterostructure and in 5 and 13nm thick GaAs/Al<sub>x</sub>Ga<sub>1-x</sub>As quantum wells. In contrast to earlier work we do not trace the cooling of hot carriers in a cold lattice but we look at the reverse process of heating of a cold electron-hole plasma by a warm lattice. The scattering rates prove to be independent of density, dimensionality, and quantum well thickness. (Author abstract) 15 refs.

**094135 BALLISTIC ELECTRON TRANSPORT IN GaAs/AlGaAs TUNNELING JUNCTIONS WITH OPTICAL PHONON EMISSION.** Oscillatory current-voltage characteristic with period of longitudinal optical-phonon (LO-phonon) energy in Hickmott's experiment (Hickmott and coworkers 1984) is studied. The origin of this oscillation is attributed to a one-dimensional localization. It can cause considerable space charge in a fieldless undepleted region. This space charge may induce an additional electric field on the barrier and therefore influence the tunneling current. Sideband energy spectrum of a tunneling electron with LO-phonon emission is given by using the path integral method and WKB approximation. Experiments are discussed. (Edited author abstract) 16 refs.

**094136 DOUBLE RIDLEY-WATKINS-HILSUM-GUNN EFFECT IN COMPENSATED GaAs.** Our studies show that impurity scattering drastically reduces low-field electron mobility, peak velocity and negative differential mobility in compensated GaAs. Under certain conditions, such as at low temperature, high doping density and high compensation ratio, the electron velocity versus electric field relation may exhibit two maxima. The reason for the second maximum is the decrease in impurity scattering rate with an increase in the kinetic energy of L-valley electrons, and subsequent electron transfer into the X-valleys. We influence the characteristics of high field domains in compensated GaAs. (Edited author abstract) 13 refs.

Xu, Jingming (Univ of Toronto, Toronto, Can); Shur, Michael. *Solid State Electron* v 31 n 3/4 Mar/Apr 1988 p 607-610.

**094137 NORMAL AND HOT ELECTRON MAGNETO-PHONON RESONANCE IN A GaAs-HETEROSTRUCTURE.** Linear and nonlinear magneto-phonon resonances are investigated in a two-dimensional electron gas in a GaAs-Al<sub>x</sub>Ga<sub>1-x</sub>As heterostructure, within the momentum balance equation approach. The linear transverse resistivity as obtained from the present approach reduces to the high magnetic field result as based on the Kubo-formula. The Landau-level broadening is taken to be a Gaussian with a constant background. The effect of the broadening parameters on the shape of the magneto-phonon oscillations in the transverse resistivity  $\rho_{xx}$  and the energy relaxation rate is found to be appreciable and stronger than in the corresponding three dimensional case. The nonlinear momentum balance equation is solved for arbitrary average electron velocity. We find that the maxima at the linear magneto-phonon resonance evolve to minima (and the minima become maxima) when the average electron velocity is sufficiently large. (Author abstract) 18 refs.

Warmenbol, P. (Univ of Antwerp, Wilrijk-Antwerpen, Belg); Peeters, F.M.; Devreese, J.T. *Solid State Electron* v 31 n 3/4 Mar/Apr 1988 p 771-775.

**094138 LOCAL DENSITY VALENCE BAND OFFSET IN GaAs/AlAs: ROLE OF INTERFACE DIPOLE.** The valence band offset,  $\Delta E_v$ , at the lattice-matched GaAs/AlAs(001) interface is derived from

highly precise self-consistent all-electron local density band structure calculations of the  $(\text{GaAs})_n(\text{AlAs})_n(001)$  superlattices (with  $n < 3$ ). Using the core levels as reference energies, we find that  $\Delta E_v = 0.50 \pm 0.05$  eV, in agreement with recent experimental results ( $\Delta E_v = 0.45 - 0.55$  eV). The dependence of  $\Delta E_v$  on the superlattice thickness is studied and related to the interface charge redistribution which produces an interface dipole potential estimated to be approximately 0.14 eV. (Edited author abstract) 12 refs.

## Plasmas

**094139 INFLUENCE OF CARRIER LIFETIME ON THE COOLING OF A HOT ELECTRON-HOLE PLASMA IN GaAs.** The influence of carrier lifetime on the cooling of a hot electron-hole plasma in bulk GaAs is studied by time-resolved photoluminescence. We observe a reduced cooling rate for samples with short carrier lifetime and an enhanced cooling rate for samples with long lifetime at high densities. The cooling rate is independent of carrier lifetime at low densities. The experimental data are in agreement with theory if the degeneracy of the electron and hole Fermi gas is taken into account. (Author abstract) 9 refs.

Leo, K. (Max-Planck-Inst fuer Festkoerperforschung, Stuttgart, West Ger); Ruehle, W.W. *Solid State Commun* v 62 n 9 Jun 1987 p 659-662.

**094140 ELECTRON PLASMA IN A NON-PARABOLIC CONDUCTION BAND.** The electron plasma in highly n-doped GaAs and InP is influenced by the nonparabolicity of the conduction band. Its properties for densities up to  $2 \cdot 10^{19} \text{ cm}^{-3}$  have been studied experimentally by Raman scattering of coupled plasmon-LO-phonon modes. The Raman spectra and the dispersion of the plasmon-phonon modes were described by evaluating the Lindhard-Mermin dielectric function including the nonparabolicity of the band structure with the carrier concentration and the electron collision time as the only free parameters. It turns out that this procedure is a very sensitive method to determine the carrier concentration of a sample. (Author abstract). 8 Refs.

## Protective Coatings

**094142 OXIDATION OF GaAs WITH A PbS LAYER ON ITS SURFACE.** Using the methods of IR spectroscopy, X-ray spectral analysis and mass spectrometry, it is shown that in the oxidation of GaAs-PbS structures the formation of  $\text{PbSO}_4$  occurs first and then that of  $\text{PbO}$ , which can then oxidize the gallium in the substrate. The rate of formation of oxide layers during thermal oxidation of GaAs-PbS structures and their electrical strength are higher than those of the oxide layers forming during thermal oxidation of GaAs. 13 refs. In Russian.

**Radiation Effects** See Also SEMICONDUCTOR MATERIALS—Radiation Effects.

**094146 DEFECT FORMATION IN NUCLEAR-ALLOYED GALLIUM ARSENIDE.** Precision methods of measuring the lattice spacing and density of single crystals were used to examine the nature and behavior of point defects in nuclear-alloyed gallium arsenide. It is shown that the main part of the interstitial atoms is not concentrated in elongated clusters of the type of disordered regions and is distributed in the matrix in the form of complexes or small clusters. Satisfactory agreement was found between the dose dependence of the lattice spacing in the irradiated material and the results of calculations based on the given defect formation model. The lattice spacing and density of nuclear-alloyed gallium arsenide are restored at an annealing temperature of 500-600°C. (Author abstract) 7 refs.

**094148 PHONON SHIFTS IN ION BOMBARDED GaAs: RAMAN MEASUREMENTS.** When 15 MeV ions bombarded single crystal GaAs (111), (100), and (110) faces, they leave a strained, crystalline, surface layer with many defects (as well as a buried amorphous layer). Using Raman spectroscopy, we measure the shifts and line widths of the optic phonons of these strained crystalline layers. Using simple models, the possible sources of the phonon shifts are quantitatively considered. We conclude that the strains, and a change in the ionic plasma frequency (LO-TO splitting) due to a ratio of interstitials, or antisites, to atoms in the crystal of  $\approx 2\%$ -3% account for the major portion of the phonon shifts. These effects have been ascribed previously to phonon confinement. (Author abstract) 34 refs.

Burns, Gerald (IBM, Yorktown Heights, NY, USA); Dacol, F.H.; Wie, C.R.; Burstein, E.; Cardona, M. *Solid State Commun* v 62 n 7 May 1987 p 449-454.

**094149 TYPE-CONVERSION PHENOMENON IN ELECTRON-IRRADIATED GaAs.** The authors examine type-conversion in more detail. It is shown that the type-conversion data are consistent with the recent TDH conclusions only if E1 is a donor. It is shown that E2 is almost certainly a donor also. These results then lead to a more accurate value for the  $C_{AS}$  production rate,  $5.0 \pm 0.5 \text{ cm}^{-1}$ , under 1 MeV irradiation. Finally, it is shown that significant room-temperature acceptor annealing can be observed in p-type samples. The possible identification of the  $C_{AS}$  with Ga-sublattice damage is discussed. 13 refs.

Look, D.C. (Wright State Univ, Dayton, OH, USA); Farmer, J.W. *J Phys Chem Solids* v 49 n 1 1988 p 97-102.

**094150 ELECTRON TRAPS IN n-GaAs IRRADIATED WITH HIGH ELECTRON BEAM FLUXES AT HIGH TEMPERATURES.** High-temperature induced defects (HTID) in GaAs have been investigated after irradiation at 50°C and 400°C. DLTS spectra of vapor phase epitaxy grown (VPE) n-GaAs ( $n = (2 \text{ to } 4) \times 10^{15} \text{ cm}^{-3}$ ) have been studied after electron bombardment with subsequent post-irradiation annealing up to 400°C. P1 to P3 traps are the primary defects of electron bombardment which are masked by E3 to E5 traps. Post-irradiation annealing or high temperature irradiation manifests HTID. 6 refs.

Brudnyi, V.N. (VD Kuznetsov Siberian Physico-Technical Inst, Tomsk, USSR); Peshev, V.V. *Phys Status Solidi A* v 105 n 1 Jan 1988 p K57-K60.

**094151 POINT DEFECTS IN GaAs STUDIED BY CORRELATED POSITRON LIFETIME, OPTICAL, AND ELECTRICAL MEASUREMENTS. II. POINT DEFECTS IN GaAs IRRADIATED WITH FAST NEUTRONS.** The positron lifetime technique was used in combination with infrared absorption, photoluminescence, and photoreflection measurements to investigate defects created by irradiation of GaAs with fast neutrons. The integrated fluence ranged from  $5 \times 10^{14}$  to  $3.8 \times 10^{19} \text{ n}^+/\text{cm}^2$ . Geometrical size of the displacement cascades is estimated to be  $r = 5 \text{ nm}$ . The behavior of the carrier concentration  $n$  estimated from photoreflection experiments provides  $r = 20 \text{ nm}$ . This value is characteristic of the insulating region surrounding the cascade. Almost the same value is typical of the luminescence killer region and positron trapping. Evidence of positron trapping by vacancy-type irradiation defects is given. The vacancies disappear in an annealing stage at 500°C. The stage is

interpreted as a long-range migration of point defects resulting in a dissolution of the displacement cascades. A substage at 200°C observed in photoluminescence experiments is discussed as recombination of vacancy-interstitial close pairs in the As sublattice which are situated outside of displacement cascades. (Edited author abstract). 34 Refs.

**094152 EFFECT OF ION BEAM MIXING ON THE EVOLUTION OF ARSENIC FROM THE Au-GaAs SYSTEM.** Gold and gold-based alloys are frequently used as contact materials to GaAs. The contact technology involves high temperature heat treatment. This temperature can be decreased using low dose ion beam mixing to break up the contaminating layer at the interface before annealing. The contact thus formed is more uniform and the gold does not penetrate so deep as in the non-implanted case. In this study a comparison of the arsenic loss from non-implanted and 700 keV  $10^{14}\text{Xe}^{2+}$  cm<sup>-2</sup> pre-implanted 40 nm Au-GaAs structures is presented. In investigating the interdiffusion of Au and GaAs by Rutherford backscattering spectrometry, different mechanisms were found for the two cases. 4 Refs.

**094154 SUPPRESSION OF RAMAN SCATTERING BY INTERFACE PHONONS IN QUANTUM WELLS UNDER HIGH PHOTOEXCITATION.** We report on the power-density dependence of resonant Raman scattering by interface phonons in GaAs-Al<sub>x</sub>Ga<sub>1-x</sub>As quantum wells. Strong photoexcitation leads to suppression of the nominally forbidden (defect-induced) scattering. The magnitude of the quenching is largest for laser energies in the vicinity of outgoing resonances. Alternative mechanisms which partially account for the experimental findings are discussed. We consider in particular the role of ionized impurities and effects due to screening by photoexcited carriers. (Author abstract) 19 refs.

## Soldering

**094155 SUCCESSFUL ALLOY ATTACHMENT OF GAAS MMIC'S.** Alloy attachment of GaAs monolithic circuits was examined after initial reflow, after environment bake, and after a stepped series of thermal cycles from 200 to 1000 cycles (-55 to +125°C). The variety of solders tested included both pastes and preforms. Monolithic assemblies alloyed with these solders were evaluated for changes in physical properties as well as for changes in electrical performance. It was noted during the study

that via fractures due to thermal expansion differences between the alloy and the GaAs monolithic device were a common occurrence and could become an inherent reliability risk. Based on this evidence, an investigation relating the frequency of fracturing to the size and the shape of the vias was undertaken. The results of the investigation led to the development of processing parameters which could minimize and control fracture occurrence; these parameters are presented.

## Solubility

**094156 SOLUBILITY OF GALLIUM ARSENIDE IN BISMUTH-GALLIUM MELTS.** The solubility of GaAs in melts of the Bi-Ge system was determined at 700, 800 and 850°C. All the liquidus isotherms were found to be characterized by the presence of a minimum at a Bi content in the solvent of approximately 85 at.% and a maximum at a Bi concentration of approximately 10 at.%. The experimental data do not agree with a calculation within the framework of a regular associated solution model. An expression is obtained for the solubility of As in the 600-900°C range for the quasi-binary system Bi-GaAs. In Russian. 13 refs.

**094157 STUDY ON DETECTIVE SENSITIVITY OF PHOTOTHERMAL RADIOMETRY SPECTROSCOPY.** The detective sensitivity of the photothermal radiometry (PTR) spectrum technique is discussed and the absorption edges of Cu<sub>2</sub>O and GaAs are measured. The absorption edge of Cu<sub>2</sub>O shows two shoulders obviously in 632nm and 641nm. The fundamental absorption edge of GaAs is measured with PTR. The signal amplitude of GaAs is an order of magnitude less than that of Cu<sub>2</sub>O. By comparison and analysis, it is found that the detective sensitivity of PTR can be improved obviously when the responsive wavelength range of infrared detector lies in the strong infrared radiation band of the specimen. **094159 RAMAN PIEZOSPECTROSCOPIC STUDY OF INDIUM-HARDENED GaAs.** We have investigated the effect of a uniaxial stress on the transverse optical and longitudinal optical phonon frequencies of In-hardened GaAs using a cw Nd:YAG laser. We find that for a stress along [1 1 1] the singlet-doublet phonon frequency splittings are smaller in comparison with those in pure GaAs. A possible explanation of this effect may lie in a hardening of the internal stress parameter due, at least in part, to the increase in lattice constant. Plastic deformation and fracture at the highest stresses reached is also discussed and compared with observations for pure GaAs. (Author abstract) 27 refs.

**094160 VERY HIGH PURITY GaAs: FREE EXCITON DOMINATED 5K PHOTOLUMINESCENCE AND MAGNETOPHOTOLUMINESCENCE SPECTRA.** We report the observation of 5K photoluminescence (PL) spectra of undoped GaAs, grown by molecular beam epitaxy, which are dominated by free exciton (intrinsic) emission. The weakness of impurity related features is taken as an indication of very low levels of residual impurity contamination. The identification of the strong, narrow peak in the PL spectra with the free exciton emission has been confirmed using magnetophotoluminescence studies. Our results are in good agreement with magnetoreflectance data which are sensitive only to intrinsic (i.e. excitonic) features. (Author abstract) 9 refs.

**094161 PHOTO-MODULATING ABSORPTION SPECTROSCOPY OF SEMICONDUCTORS UNDER HYDROSTATIC PRESSURE.** A technique for the photo-modulating optical absorption spectrum under hydrostatic pressure is developed. This new experiment method which combines the highly sensitive modulation spectroscopy with the diamond anvil cell technique is very useful for investigating the absorption of interband transitions in semiconductors under extreme conditions. The new technique has been used for GaAs and CdTe and shows superiorities of the sensitivity and accuracy to the conventional optical absorption spectroscopy under high pressure. (Author abstract) 11 refs.

**094162 CHARACTERIZATION OF ELECTRICAL PROPERTIES OF SEMI-INSULATING GaAs USING ACOUSTO-ELECTRIC VOLTAGE SPECTROSCOPY BETWEEN 83 AND 300 K WITH SURFACE WAVE POWER AS AN ADDITIONAL PARAMETER.** Transverse acousto-electric voltage (TAV) measurements as a function of incident photon energy, surface acoustic wave (SAW) power and dc bias voltage of temperature range between 83 and 300 K are used to study the surface of semi-insulating, Cr-doped GaAs samples. A bound excitonic excitonic level around 1.506 eV is detected and it is observed that (i) raising the temperature, (ii) applying a dc bias voltage, (iii) increasing the SAW power, (iv) decreasing the spectral resolution of the incident photon beam and (v) illuminating by a bias light with energies between 1.55 and 0.89 eV all result in the quenching of the excitonic structure. The presence of a large band of interface traps, that considerably influences the field effect measurements, are detected and their radial distribution is studied by monitoring the TAV amplitude as a function of the spatial position of the incident beam. (Edited author abstract) 24 refs.

**094163 PHOTOREFLECTANCE SPECTROSCOPY OF GaAs-AlAs MULTIPLE QUANTUM WELL STRUCTURES.** Photoreflectance (PR) spectra of GaAs-AlAs multiple quantum well (MQW) structures at room temperature are measured and compared with the photoluminescence excitation spectrum at 2K. The results show that the excitonic process is very important for GaAs-AlAs MQWs even at room temperature. The PR modulation mechanism of GaAs-AlAs MQW structures is discussed. It is pointed out that the PR modulation is mainly caused by the optical modulation of the surface electric field. In contrast to the case of bulk materials, the PR spectra of MQWs have mainly the first derivative functional lineshapes. Under the low field condition, they

are dominated by the stark shifts of quantized subbands and corresponding excitonic energy gaps. (Author abstract). 17 Refs. In Chinese.

**094164 RAMAN SCATTERING FROM PERIODIC & QUASIPERIODIC GAAS/GA<sub>1-x</sub>AL<sub>x</sub>AS SUPERLATTICES.** The Raman spectra of periodic and Fibonacci superlattices of GaAs/Ga<sub>1-x</sub>Al<sub>x</sub>As are reported. The superlattices were grown using similar bilayer building blocks involving layers of GaAs and Ga<sub>1-x</sub>Al<sub>x</sub>As of different thicknesses. Like the more usual superlattices grown from unilayer blocks, the frequencies of the longitudinal acoustic modes observed in the Raman spectra depend strictly on the superlattice periodicity (or quasiperiodicity). However, the Raman intensities of the acoustic modes in the bilayer superlattices differ from predictions based on theories for the unilayer cases. The optic-mode Raman spectra of the periodic and quasiperiodic superlattices are very similar apart from the intensity of the GaAs-layer longitudinal optic phonon at 290 cm<sup>-1</sup>. (Author abstract). 21 Refs.

**094165 MASS SPECTROSCOPIC STUDY OF THE PYROLYSIS OF ORGANOMETALLIC PRECURSORS USABLE IN GAAS VAPOR PHASE EPITAXY. I: THE FLUORINE-CONTAINING DERIVATIVES (C<sub>6</sub>F<sub>5</sub>)<sub>3</sub>-N<sub>2</sub>ME<sub>2</sub>GAASET<sub>3</sub>.** Thermal decomposition of the coordination compounds Rf<sub>3-n</sub>Me<sub>n</sub>GaAsEt<sub>3</sub> (Rf=C<sub>6</sub>F<sub>5</sub>; n=0, 2) in a CVD reactor has been investigated under helium and hydrogen atmosphere by a quadrupole mass analyzer. At 600°C, hydrogen facilitates the Rf elimination forming C<sub>6</sub>F<sub>5</sub>H but under inert atmosphere, decomposition of these cyclic groups generates HC≡CF and stable gallium fluoride entities which prevent, in the case of Rf<sub>3</sub>GaAsEt<sub>3</sub>, the growth of the layer. The ethyl elimination mechanism is a β elimination for RfMe<sub>2</sub>GaAsEt<sub>3</sub> in helium, hydrogenolysis and homolytic fission followed by disproportionation of Et radical for RfMe<sub>2</sub>GaAsEt<sub>3</sub> in hydrogen. The reaction mechanism becomes complicated for Rf<sub>3</sub>GaAsEt<sub>3</sub> in helium. The electroattractive Rf group stabilizes the donor-acceptor Ga-As bond as this is required for adducts used as a single source but its use as ligand in organometallic precursor for GaAs epitaxy must be limited according to its low thermal stability. (Author abstract). 18 Refs.

**094166 MASS SPECTROMETRIC STUDY OF THE PYROLYSIS OF ORGANOMETALLIC PRECURSORS USABLE IN GAAS VAPOR PHASE EPITAXY. II: THE DIARSINE ADDUCTS [CIR<sub>2</sub>GAA-SET<sub>2</sub>]<sub>2</sub>CH<sub>2</sub> (R=Me, Et).** The thermal decomposition of adducts [CIR<sub>2</sub>GaAsEt<sub>3</sub>]<sub>2</sub>CH<sub>2</sub> (R=Me, Et) in helium and hydrogen atmosphere has been investigated by mass spectrometry. Using a simple analytical procedure, this paper reveals the importance of the alkyl elimination process in epitaxial growth. Hydrogen would favor homolytic fissions of M-Et bonds, whereas a β elimination would be dominant at higher temperatures. The first mechanism seems preferable in low temperature GaAs OMVPE to a β elimination which generates both hydride intermediates and a polycrystalline growth if the deposition temperature is not sufficiently high. Selection of useful new precursors requires thermolabile groups and must take in account these competitive alkyl elimination mechanisms. (Author abstract). 17 Refs.

**094167 ANGLE-DEPENDENT X-RAY PHOTOELECTRON SPECTROSCOPY INVESTIGATION OF GAAS SURFACES.** Angle-dependent x-ray photoelectron spectroscopy (ADXPS) provides a method for investigat-

ing thin native oxides without the need for destructive depth profiling. In addition, surface chemical environments can be identified and their chemical shifts monitored as a function of angle. The ability to examine samples at very small angles is important if the types and extents of surface coverage are to be distinguished between. A study of the growth of native oxide on a GaAs surface by ADXPS shows the oxide to be gallium rich at the outermost surface. Comparison of the data with theoretical models for thickness and extent of coverage indicates that the oxides grow as patches of variable thickness. (Author abstract) 10 refs.

**094175 INTENSITY CORRELATION MEASUREMENT OF TIME-RESOLVED PHOTOLUMINESCENCE FROM GAAS MQWS.** We have measured the energy relaxation of hot carriers in p- and n-type GaAs/GaAlAs quantum wells by detecting time-resolved hot luminescence using two-pulse intensity correlation with 150fs resolution. In the former p = 7 × 10<sup>17</sup> cm<sup>-3</sup> and the well width d<sub>w</sub> = 60 Angstrom; the n-type sample has n = 2 × 10<sup>17</sup> cm<sup>-3</sup> and d<sub>w</sub> = 258 Angstrom. The excitation density is approximately 3 × 10<sup>16</sup> cm<sup>-3</sup>, and the photon energy hν = 2.0 eV. Assuming that the photon excess energy is shared evenly among the carriers, the initial mean carrier energy is approximately 14 meV for the p-type sample and 62 meV for the n-type sample. 4 refs.

**094188 PHOTOLUMINESCENCE FROM DEFECTS AND IMPURITIES IN GaAs/n-GaAlAs 2DEG STRUCTURE.** A great effort has been paid to improve the quality of the 2DEG structure. The growth defects and unintentional impurities such as carbon are regarded as two important factors to influence electron mobility and hard to be controlled in MBE technology. For analysing the type of defects and impurities and their relative concentrations, photoluminescence is a sensitive and very useful technique. The 2DEG sample was grown on (100) oriented Cr-doped GaAs substrate. The photoluminescence measurement was carried out at 4.2K by using Ar<sup>3+</sup> laser 5145 Angstrom emission with power density about 0.2w/mm<sup>2</sup>. 4 refs.

**094189 PHOTOLUMINESCENCE RELATED TO THE INTERFACE OF GaAs/(GaAl)As HETEROJUNCTIONS.** We have investigated an unusual new line observed in GaAs/(AlGa)As heterojunctions, referred to as the H-band, by low-temperature photoluminescence experiments in magnetic fields up to 9.5 T. The direction of the magnetic field was turned from perpendicular to parallel to the interface. From the energetic shift, the splitting-behaviour, the lineshape and the temperature dependence of the luminescence line, we conclude that the H-band is emitted by the recombination of a flat-band electron with a hole confined to an excited subband. (Author abstract) 2 refs.

**094190 EVIDENCE FROM PHOTOLUMINESCENCE SPECTRA FOR THE FORMATION OF EXTREMELY LOW-COMPENSATED P- AND N-TYPE Ge-DOPED GaAs GROWN BY MOLECULAR BEAM EPITAXY.** Photoluminescence (PL) spectra of molecular beam epitaxially-grown GaAs doped by an amphoteric impurity (Ge) are reported. PL results re-

vealed that significantly low-compensated both n- and p-type samples can be reproducibly fabricated by precisely controlling As<sub>4</sub> to Ga flux ratio,  $\gamma$ . It was also explicitly demonstrated that along the increase of  $\gamma$ , a steep change from p- to n-type conduction occurs at  $\gamma$  about 1.6. (Author abstract) 2 refs.

**094191 DETECTION OF FIR RADIATION BY PHOTON DRAG OF FREE CARRIERS IN SEMI-METAL THIN FILM.** Fast ns. response with good sensitivity of far infrared radiation (FIR) is observed in anisotropic thin films of Bi and Sb evaporated at large angle. The signal in the wavelength region  $\lambda > 200 \mu\text{m}$  is assigned to the classical optical pressure on the free carriers while the signal in the 100 microns region can be assigned to a band transition. These detectors are currently used by us for time diagnostic of FIR laser Raman with a sensitivity 10-20 times larger than the best commercial Ge photon-drag detectors at wavelengths larger than 300 microns. (Author abstract) 23 refs.

## Strain

**094192 EFFECTS OF PLASTIC STRAIN ON THE ELECTRICAL PARAMETERS OF GaAs.** A logical explanation has been obtained for the experimental results for the EL2 centers produced on plastic strain. Our object has been to obtain a fuller picture of the conductivity of strain GaAs, where we have used semi-insulating s/i GaAs, as well as n-type and p-type specimens. An important point is the number of possible dislocation states, which is estimated as  $n_d = 2N_d/b$  ( $b$  is the Burgers vector). For each crystal, we used at least one specimen such that  $n_d$  was 10 times larger than the major-carrier concentration in the unstrained material. 17 refs.

**Structure** See Also SEMICONDUCTING GALLIUM COMPOUNDS—Structure.

**094193 INVESTIGATION OF THE STRUCTURE OF THE  $2 \times 4$  RECONSTRUCTIONS OF GaAs (001) BY ANALYSIS OF RHEED INTENSITY DATA.** Rocking curves are computed for electrons incident in turn in three different azimuths for 512 different models of the reconstruction. Each model corresponds to a different arrangement of twisted tilted dimers. For each incident beam azimuth many of these distinct models give identical rocking curves. This is explained by the possible values of the structure factor for scattering by surface atoms. In particular it is shown that the incident electrons are insensitive to atomic displacements which are parallel to the incident beam azimuth. Preliminary models are presented for which the agreement with experiment is best for all three azimuths. The effects of tuning the displacements within the dimers are considered and finally the intensities of the non-specular beams are briefly discussed. (Edited author abstract) 10 refs.

**094194 RAMAN SPECTROSCOPY OF ACOUSTIC PHONONS IN FIBONACCI SUPERLATTICES.** We report on resonant and non-resonant Raman scattering by acoustic phonons in Fibonacci GaAs-AlAs superlattices. Spectra off-resonance show doublets centered at frequencies that follow a power-law behavior, in good agreement

with predictions of a continuum model. Resonant data show a weighted density of states revealing the expected rich structure of gaps in the phonon spectrum. It is proposed that the electronic excitation involved in the resonant process is a surface state of the superlattice. (Author abstract) 23 refs.

**094196 DECAPAGE IN SITU DE SUBSTRATS GaAs (001) PAR HCl GAZ.** [In Situ Cleaning of GaAs (001) Substrates Using HCl Gas]. In situ chemical etching of GaAs (001) by gaseous HCl before molecular beam epitaxy growth has been studied by X-ray Photoelectron Spectroscopy (XPS) and Secondary Ion Mass Spectrometry (SIMS). At low temperature (25°C) under high HCl partial pressure, HCl only removes the oxide layer of the substrate and does not react with the underlying GaAs crystal. At high temperature (> 400°C) under low pressure, the GaAs substrate is etched at a rate of 6  $\text{\AA}/\text{min}$ . However, SIMS analysis shows a highly contaminated substrate-layer interface after etching at 400°C. (Edited author abstract) 5 refs. In French.

Contour, J.P. (CNRS, Valbonne, Fr); Massies, J.; Huber, A.; Grattepail, C. *Vide Couches Minces* v 43 n 241 Mar-Apr 1988, 2emes Journ Etud sur L'Epitaxie et la Passivation des Composés III - V, Fr, Apr 27-28 1988 p 167-168.

**094197 QUALIFICATION DE SUBSTRATS DE GaAs SEMI-ISOLANTS.** [Qualification of Semi-Insulating GaAs Substrates]. A brief review of different kinds of semi-insulating materials available and the suppliers presently on the market is given. The qualification is discussed in terms of wafer morphology, polishing quality and electrical properties; in all cases, a quantitative approach is proposed in order to avoid misunderstandings with the suppliers. Some other points such as subsurface-damages and thermal stability are discussed and analyzed as non-objective parameters. This qualification is presented as necessary but not sufficient. The future requires definition of more precise criteria based on a better understanding of semi-insulating GaAs. (Edited author abstract) 8 refs. In French.

**094199 SOLID-PHASE REACTIONS BETWEEN (100) GaAs AND THIN-FILM REFRACTORY METALS (Ti, Zr, V, Nb, Cr, Mo, AND W).** Recently, there has been an increased interest in the applications of refractory metals as gate materials for the self aligned gate process in the fabrications of GaAs field effect transistors. In this study, we systematically investigated the thermally induced interface interactions between (100) GaAs substrates and thin films of refractory metals (Ti, Zr, V, Nb, Cr, Mo, and W). Depth profilings of the M/GaAs interfaces were obtained using conventional and heavy ion Rutherford backscattering spectrometry. Phase identifications were achieved by X-ray diffraction. Results on the phase formation sequence, reaction kinetics, the distribution, composition and structure of the reacted phases and the interface reactivity of these contacts are presented. Correlations between metal properties (electronegativity and metal-metal bond strength) and kinetics of the reactions (activation energy and reactivity of the interfaces) are discussed. (Author abstract) 36 refs.

**094200 QUALITATIVE ANALYSIS OF INTERFACIAL PHENOMENA AT THE UNDOPED POLY-GaAs/KCl SOLUTION INTERFACE USING MICROELECTROPHORESIS MEASUREMENTS.** The author describes a relation between interfacial charges at undoped semiconductor/electrolyte interfaces and zeta potentials, and discuss the surface states and interfacial phenomena with reference to microelectrophoresis experiments. Experiments indicate that the effect of grain boundaries in poly-semiconductor is not important and can be neglected for colloidal semiconductors. The density of the slow surface states of the undoped poly-Si is greater than that of undoped poly-GaAs. The  $\text{K}^+$  and  $\text{Cl}^-$  ions at the undoped poly-GaAs/KCl solution interfaces are indifferent ions and the KCl solutions are indifferent electrolytes. The slow surface states of undoped poly-GaAs/KCl solution interfaces are dominated by the physically adsorbed  $\text{K}^+$  ions which act as positively charged donor surface states. 25 refs.

**094201 OXIDATION STATES AND FERMI-LEVEL PINNING ON GaAs(110) SURFACE.** Fermi-level pinning produced by oxygen adsorption on the GaAs(110) cleavage surface both at 300 (in chamber) and 77 K (in liquid  $\text{N}_2$ ) has been studied using the polarization modulated reflectivity technique. Specific transformations of spectra of doped samples have made it possible to follow the kinetics of barrier formation. It has been found that the creation of acceptor and donor pinning levels on the surface correlates with two essentially different oxida-

tion states. The first is the chemisorption of atomic oxygen. We suggest that it forms patches on the surface. The second phase is supposed to be a surface oxide. (Edited author abstract) 34 refs.

**094203 ELECTRONIC PROPERTIES AND MODELING OF LATTICE-MISMATCHED AND REGROWN GaAs INTERFACES PREPARED BY METALORGANIC VAPOR PHASE EPITAXY.** In order to study and model non-ideal semiconductor-semiconductor interfaces, three kinds of GaAs interfaces, i.e., (i) a slightly mismatched InGaAs/GaAs interface, (ii) a highly mismatched GaAs/InP interface and (iii) an air-exposed GaAs/GaAs interface, were prepared by MOVPE. Their electronic properties were studied through measurements of C-V characteristics, carrier concentration profiles, DLTS spectra and I-V characteristics. By a novel interpretation of C-V characteristics and DLTS spectra, all the experimental results were explained consistently by a common model involving a U-shaped interface state continuum. The origin of the interface state continuum is explained by the disorder induced gap state (DIGS) model recently proposed for insulator-semiconductor and metal-semiconductor interfaces. This model seems to serve as a universal model for non-ideal S-S interfaces. (Author abstract) 18 refs.

**094205 OXYGEN ON AND BELOW THE 001 SURFACES OF GALLIUM ARSENIDE.** A tight binding slab model calculation is used to simulate the electronic structure about a layer of oxygen on and below the unrelaxed 001 surface of gallium arsenide. Comparison is made with photoemission data. The results lead to a simple interference model which could present an explanation as to why electrons are pinned about a constant energy position in the gap at high levels of oxygen exposure. (Author abstract) 9 refs.

Lowther, J.E. (Univ of Witwatersrand, Johannesburg, S Afr). *Solid State Commun* v 66 n 1 Apr 1988 p 75-77.

**094206 DETERMINATION DES ETATS DE SURFACE INDUITS PAR UN METAL ELECTRODEPOSE A LA SURFACE DE GaAs PAR MESURE DE PHOTOCAPACITE.** [Determination of Surface States Induced by Metal Electrodeposited on Sur-

faces of GaAs by Photocapacity Method]. The method of photocapacity used with electrochemical junctions is studied as the mechanism of formation of metal/semiconductor interfaces. The method is used for n-GaAs/metal-electrolyte interface. The electrolytic deposition of metal on GaAs substrate permits one to obtain Schottky barrier with electric characteristic comparable to ultra-high vacuum technique. 4 refs. In French.

Allongue, P. (CNRS, Paris, Fr). *Vide Couches Minces* v 43 n 241 Mar-Apr 1988, 2emes Journ Etud sur L'Epitaxie et la Passivation des Composés III - V, Fr, Apr 27-28 1988 p 259-260.

**094207 APPLICATION DE L'XPS ANGULAIRE A L'ETUDE DE LA PASSIVATION DE SEMI-CONDUCTEUR (Si -  $SiO_2$ , GaAs - OXYDES NATIFS).** [Application of Angle-Resolved X-Ray Photoelectron Spectroscopy to the Passivation of Semiconductors (Si- $SiO_2$ , GaAs - Native Oxide)]. Analysis by measurements under different take-off angles of photoemitted electrons excited by X-rays provides chemical information about the surface region of materials. It is possible to extract quantitative results about the concentration of elements as a function of depth. In a first step a series of experiments have been performed on samples of silicon thermally oxidized to check the validity of this analytical method. The experimental results for the interface thickness are found to be in good agreement with other results. The studies of GaAs were performed on the (001) face of the sample. The anisotropies in angular photoemission were found mainly for  $As_{3d}$  and  $As_{3d}/Ga_{3d}$ . An analysis by decomposition of experimental peaks by means of a curve-fitting routine gives a combination of gaussians. The comparison between the intensities of  $As_{3d}$ ,  $Ga_{3d}$  and  $O_{1s}$  peaks points out the presence in high proportion of Ga or As atoms non-combined with oxygen or in the form of suboxides. (Edited author abstract) 9 refs. In French.

Quemerais, A. (CNRS, Rennes, Fr); Lepert, S.; Gaudu, M.L.; Priol, M. *Vide Couches Minces* v 43 n 241 Mar-Apr 1988, 2emes Journ Etud sur L'Epitaxie et la Passivation des Composés III - V, Fr, Apr 27-28 1988 p 277-278.

**094208 CONDUCTIVITE DE SURFACE SUR GaAs ET D'INTERFACE GaAs/NITRURE.** [Conductivity of the GaAs Surface and the GaAs/Nitride Interface]. The authors have investigated the conductance of  $Si_3N_4$ /GaAs interfaces between two types of contacts, ohmic and Schottky. The surface square resistance was found to be  $10^{10}$  ohms, about one order of magnitude below the square resistance of free GaAs surface, and it is poorly dependent on surface treatment and type of contact. The free surface conductance is recovered at low voltage when a recess is realized before the Schottky metallization. These results are qualitatively in good agreement with the discussion of conductance transient measurement on GaAs Mesfet previously published. (Author abstract) 3 refs. In French.

**094210 MONTE CARLO SIMULATION OF HOT ELECTRONS IN n-GaAs. EFFECT OF ELECTRON-ELECTRON SCATTERING ON DRIFT VELOCITY OVERSHOOT.** Monte Carlo simulation is presented to clarify the screening effect of the polar LO phonon scattering field by electrons on the high field transport in GaAs. The electron-electron scattering (short range force) is also examined, where the long range interaction, electron-plasmon scattering, is not considered. The conventional Monte Carlo simulation, single electron simulation, or Ensemble Monte Carlo simulation, does not take into account the simultaneous change of the two electrons' states. New Monte Carlo simulation is proposed in which simultaneous simulation of many electrons' states is made, where energy and momentum conservation is exactly taken into account. (Edited author abstract) 15 refs.

## Thermal Effects

**094211 TEMPERATURE DEPENDENCE OF THE PHOTOLUMINESCENCE IN GaAs-GaAlAs MULTIPLE QUANTUM WELL STRUCTURES.** The temperature dependence of the photoluminescence (PL) of GaAs/GaAlAs multiple quantum wells is investigated. Emissions related to transitions between  $n=1,2,3$  electron and hole subbands are observed. Theoretical evaluation of the energy levels fits nicely the experimental data. The temperature dependence of peak position and photoluminescence intensity and the dependence of PL intensity on the power excitation show that there are three different temperature regions. At low temperatures (22 to 40 K) the main emission is ascribed to exciton recombination while at temperatures higher than 100 K it can be attributed to free carrier recombination. In the intermediate temperature region the PL involves both, excitonic and free carrier recombination. Thermally activated non-radiative recombination processes strongly reduce the luminescence quantum efficiency. (Author abstract). 14 refs.

## Thermoelasticity

**094213 THERMOELASTIC ANALYSIS OF GaAs IN LEC GROWTH CONFIGURATION: II. TEMPORAL EVOLUTION OF THE STRESS FIELD.** The temperature distribution in the growth system and the elastic thermal stress field in the growing crystal are calculated at three stages of the solidification process. Results indicate that at the early stages of growth

excessive stresses are generated as the cone emerges from the encapsulant, and at later times the maximum stresses occur close to the solidification interface and the region where the crystal emerges from the encapsulant. Adjustment of heater power for reduction of stresses associated with excessive cooling of the crystal is found to be inadequate and results in enhanced convexity of the growth interface and generation of large stresses in that region. (Author abstract) 16 refs.

**094217 MODIFIED EXCITONIC RESONANCES IN GaAs/AlAs MULTIPLE QUANTUM WELL HETEROSTRUCTURES WITH ULTRATHIN BARRIERS.** Excitonic resonance structures in GaAs/AlAs multiple quantum well heterostructures with varying barrier-layer thicknesses  $L_B$  down to 1.3 nm are investigated for two sets of samples with the nominal well widths of  $L_Z=9.2$  and 6.4 nm, by 2K photoluminescence excitation spectroscopy. The observed resonance energies of the  $n=1$  heavy-hole (1 hh) and light-hole (1 lh) free excitons imply that quantum confinement effects persist at least down to the decreased barrier-layer thickness of  $L_B=1.3$  nm. This result is inconsistent with the red shifts expected from the simple well-coupling theory within the one-band Kronig-Penney model at the  $\Gamma$  point. Instead,

blue shifts of 6-8 meV (8-17 meV) are observed for the 1 hh (1 lh) excitonic resonance peaks when  $L_B$  is decreased from 10 to 2 nm. A relative decrease of the oscillator strength of the 1 lh transition compared to the 1 hh transition is also observed as  $L_B$  is decreased. These results manifest important effects of the indirect-gap barrier material for the actual wavefunction matching across the interface and the breakdown of the envelope function approach to GaAs/AlAs quantum well heterostructures with ultrathin barriers. (Author abstract) 25 refs.

**094219 INVESTIGATIONS OF THIN FILMS ON GaAs USING THE PROTON RESONANT SCATTERING TECHNIQUE.** We have characterized a number of thermally stable thin film/GaAs systems including thin films of refractory metal silicides and nitrides as well as dielectric films on GaAs substrates using a MeV proton scattering technique. Thin films of tungsten silicides, zirconium nitride and silicon dioxide on GaAs substrates are investigated. The enhanced proton scattering cross sections of nitrogen, silicon and oxygen at their corresponding resonant energies enable us to accurately measure the compositions of these films. The advantages and disadvantages of this technique regarding depth resolution, accessible depth, and mass resolution compared to the conventional Rutherford backscattering spectrometry for thin film analysis are discussed. (Author abstract) 28 refs.

**094220 ENERGY BAND STRUCTURE OF  $(\text{GaAs})_m(\text{AlAs})_n$  SEMICONDUCTOR SUPERLATTICES WITH ULTRATHIN LAYERS.** The local band structure of the  $(\text{GaAs})_m(\text{AlAs})_n$  superlattices is calculated within the framework of the cluster recursion method of Haydock-Heine-Kelly. The Hamiltonian is constructed in the  $\text{sp}^3\text{s}^*$ -basis of the tight-binding method. The diagonal matrix elements and orbital populations are calculated in a self-consistent way. The superlattice consists of alternate layers of GaAs and AlAs, each containing one to eight (110) layers of zincblende structure. The limiting cases of such a superstructure are the ideal heterojunction and a semiconductor material made up of alternate GaAs and AlAs layers. The paper presents the calculated densities of electron states for  $(\text{GaAs})_1 \cdot (\text{AlAs})_1$  and band discontinuities at the heterojunction. The dependence of the superlattice energy gap width on the alternate layer thickness derived here is in qualitative agreement with the experimental photoluminescence data. (Author abstract) 18 refs.

**094224 TRANSPORT PARAMETERS IN ILLUMINATED LAYERS OF SEMIINSULATING GaAs.** Measurements are reported on semi-insulating p-type gallium arsenide specimens illuminated with photons of energy greater than the energy gap. An excited layer is defined of thickness  $d$  given by the sum of the radiation penetration depth and the ambipolar diffusion length. Concentrations  $n$  and mobilities  $\mu$  of the carriers in this layer are determined from galvanomagnetic effects in light and in darkness. The concentration  $n$  shows a slow decrease with increasing wavelength out to the absorption edge, where it falls abruptly;  $\mu$  falls with rising photon energy. As a function of increasing intensity, the mobility remains constant, while  $n$  rises linearly with photon-excitation rate. The results are discussed in terms of the variations of  $d$ . Further an attempt has been made to find the dependence between electron and hole concentrations in the excited layer measuring the variations of short circuit photomagnetolectric current as a function of excess conductance. (Author abstract) 9 refs.

**094227 NEGATIVE MAGNETORESISTANCE OF NEUTRON-TRANSMUTATION-DOPED GALLIUM ARSENIDE AT VARIABLE-RANGE HOPPING.** Investigations of anomalous magnetoresistance (mr) in neutron-transmutation-doped GaAs are performed at  $T=0.05$  to  $4.2$  K in the vicinity of the metal-insulator transition (MIT). Without as well as with magnetic field a variable-range hopping law  $q(T)=q_0 \exp(T_1/T)^{1/2}$  is found where  $T_1$  approaches zero as  $n$  approaches  $n_c$ . At higher magnetic fields the negative mr saturates and eventually changes into a positive mr with  $T_1(H) > T_1(0)$ . The dependence of  $T_1$  on  $n$  as well as on  $H$  originates from the scaling behavior of the localization radius and the dielectric constant at the MIT. (Edited author abstract) 19 refs.

**094228 HYDRODYNAMIC HOT-ELECTRON TRANSPORT MODEL WITH MONTE CARLO-GENERATED TRANSPORT PARAMETERS.** A unique hot-electron transport model suitable for studying submicron GaAs device structures is presented. The model is based on the semiclassical 'hydrodynamic' conservation equations for the average electron density, momentum, and energy. The model includes electron relaxation times, momentum relaxation times, energy relaxation times, electron temperature tensors and heat flow vectors as a function of average electron energy for the  $\Gamma$ , X and L valleys of GaAs. The relaxation times represent rates of exchange of electrons between valleys and rates of loss of average momentum and average energy between and within the individual valleys. The electron temperature tensor and heat flow vector depend on the electron velocity distribution about the average electron velocity and ultimately affect transport when spatial variations in average velocity and average energy exist. Transport parameters are calculated using the Monte Carlo method and the ergodic principle applied directly to the integral definitions for the parameters. Therefore, the model includes nonequilibrium transport effects such as velocity overshoot and nonuniform average electron energy. The new model should prove instrumental in optimizing electron transport through submicron structures for high-speed devices. (Edited author abstract) 7 refs.

**094232 CHARACTERIZATION OF  $\text{Ga}_{1-x}\text{Al}_x\text{As}$ /GaAs SUPERLATTICES AND THIN SINGLE LAYERS BY X-RAY DIFFRACTION.** The optimization of the production conditions of laser materials on the basis of multiquantum structures as an active layer requires knowledge of the geometrical structure, chemical composition, and stress profile of the applied superlattice. These data can be established by X-ray diffraction since the periodic hyperstructure of the superlattice in the nanometer region has a detectable influence on the X-ray diffraction pattern. The characterization of superlattices by this technique is performed by an X-ray collimator. In principle it represents a double crystal diffractometer with a slit monolithic Si crystal which is an almost ideal collimator and monochromator. A theoretical consideration is given of the superlattice diffraction. Experimental results of X-ray diffraction measurements are presented. (Edited author abstract) 7 refs.

**094236 OBSERVATION OF DONOR-RELATED DEEP LEVELS IN  $\text{Ga}_x\text{In}_{1-x}\text{P}$  ( $0.52 \leq x \leq 0.71$ ).** This paper reports donor-related deep levels in  $\text{Ga}_x\text{In}_{1-x}\text{P}$  ( $0.52 \leq x \leq 0.71$ ). S-, Se- and Si-doped GaInP grown by chloride-vapor-phase epitaxy was used for the measurements. At the Ga composition  $x$  of 0.52 that is lattice matched to GaAs, a deep level was observed for S-doped GaInP but not for Se- or Si-doped GaInP. Se-doped GaInP with larger  $x$  values was also studied, and the deep level was observed for  $x$  larger than 0.56. It is found that the behavior due to these donor-related deep levels, with effects such as persistent photoconductivity and Ga-composition dependence, is the same as for DX centers in AlGaAs. These results are relevant to the use of GaInP/GaAs heterostructures for high-speed electronic devices such as high-electron-mobility transistors. (Edited author abstract) 12 refs.

## Aging

**094238 STUDY BY DDX AND SIMS OF EPVOM GROWN  $\text{Ga}_{1-x}\text{Al}_x\text{As}$ .** The aging of EPVOM grown  $\text{Ga}_{1-x}\text{Al}_x\text{As}$  layers has been studied by double X-ray diffraction in a first step. The evolution of strain measured by the radius of curvature varies from one layer to another for a same composition. The origin of this evolution is the oxidation of the layers. The oxidation can occur even for layers which are protected by a GaAs layer. In order to find a correlation between the oxidation rate and a chemical component, a SIMS study has been carried out. It shows a correlation between the carbon concentration and the oxidation rate of Al rich  $\text{Ga}_{1-x}\text{Al}_x\text{As}$  compounds. For a carbon concentration larger than a few  $10^{17} \text{ cm}^{-3}$  the oxidation rate is too small to be measured. (Author abstract) 2 refs. In French.

**094239 DRIFT MOBILITIES OF PHOTOCARRIERS IN AMORPHOUS HYDROGENATED GaP MADE BY REACTIVE EVAPORATION.** The drift mobilities of photoelectrons and photoholes in a film of a-GaP:H at 300 K were estimated to be  $2.3 \times 10^{-3} \text{ cm}^2/\text{Vs}$  and  $1.3 \times 10^{-3} \text{ cm}^2/\text{Vs}$ , respectively, from a time-of-flight measurement in which the mole ratio of Ga to P, r, in the film was nearly equal to unity. Spectra of the ac photoconductivity for different hydrogenated films with different values of r were measured at 90 K and the results at low photon energies suggest an excitation of electrons and holes at the gap states to the mobility edges of the conduction and valence bands, respectively, owing to the transport of mobile holes as well as mobile electrons deduced from time-of-flight measurements. (Author abstract) 10 refs.

**094241 SCREENING EFFECTS IN TWO-DIMENSIONAL ELECTRON GAS.** The potential produced by a charged impurity at the interface of a highly doped GaAlAs and GaAs is calculated at a finite temperature. The electron gas formed at the interface is described as a two dimensional gas in which the impurity is assumed to

be dipped. Temperature dependence of the impurity potential is calculated in the random phase approximation (R.P.A.) as well as in the modified temperature-dependent Thomas-Fermi (M.T.T.F.) approximation which is defined to include temperature effects and to reduce to Thomas-Fermi result at zero temperature. The binding energy of the impurity for the ground state is calculated in R.P.A. and in M.T.T.F. It is shown that at temperature T, much larger than the Fermi temperature,  $T_F$ , M.T.T.F. gives binding energies close to R.P.A. results. (Author abstract) 10 refs.

**094245 FEMTOSECOND ABSORPTION SATURATION STUDIES OF HOT CARRIERS IN GaAs AND ALGaAs.** Femtosecond carrier dynamics in GaAs and AlGaAs thin films are studied by time-resolved pump-probe spectroscopy. Measurements are performed using identical pulses as well as a continuum probe. Observations of the ultrafast absorption saturation response are related to the excitation of the carriers into specific nonthermal distributions, to their rapid scattering out of these states, and to subsequent cooling of the quasi-thermal carrier distribution to the temperature of the lattice. A strong dependence of the initial scattering rates on the mole fraction of Al and the excess electron energy is observed. 34 refs.

Lin, Wei-Zhu (MIT, Cambridge, MA, USA); Schoenlein, Robert W.; Fujimoto, James G.; Ippen, E.P. *IEEE J Quantum Electron* v 24 n 2 Feb 1988 p 267-275.

**094246 HOT CARRIER ENERGY LOSS RATES IN GaInAs/InP QUANTUM WELLS.** We have measured the energy loss rates of hot carriers in bulk  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As}$  and in  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As}/\text{InP}$  quantum wells of widths 154 Angstrom and 14 Angstrom. We find that the energy loss

rates are considerably lower than predicted by the unscreened carrier-LO phonon interaction. We show that the discrepancy may be resolved, at least in part, by invoking the presence of a non-equilibrium phonon distribution, the magnitude of the effect depending on the well width. (Author abstract) 15 refs.

**094249 GAS MIXING DEVICE FOR MOCVD.** Epitaxial layers of  $\text{Ga}_{1-x}\text{In}_x\text{As}$  have been grown in a horizontal, low pressure metalorganic chemical vapor deposition reactor, using a mixing manifold of radial symmetry. The effect of the inlet configuration of the reactant gases on the compositional uniformity of the layers has been investigated by photoluminescence spectroscopy. It was found that incomplete gas phase mixing of the reactants resulted in poor uniformity of the grown layers. By incorporating a mixing device in the gas line, which imparted a rotational component to the gas flow, epitaxial layer uniformities were markedly improved. (Author abstract) 6 refs.

**094251 RAMAN SCATTERING ANALYSIS OF DISORDER IN HETEROGENEOUS  $(\text{GaAs})_{1-x}(\text{SiC}_2\text{:H})_x$  FILMS GROWN BY METAL-ORGANIC CHEMICAL VAPOUR DEPOSITION.** A chemical and structural analysis of  $(\text{GaAs})_{1-x}(\text{SiC}_2\text{:H})_x$  film is performed by using the Raman scattering probe. A multizone structural model is evidenced in accordance with previous

X-ray and electron diffraction experiments. The ability of a spatial correlation model to account for the lineshape evolution of the spectra of the GaAs phase is discussed for the first time for both longitudinal optical and transverse optical modes. The values of the 'Raman size' of the GaAs crystallites lie well below those deduced from diffraction experiments, revealing the presence of many internal defects which greatly influence the electron-phonon interactions. (Author abstract) 16 refs.

Maury, F. (CNRS, Toulouse, Fr); Carles, R.; Landa, G.; Renucci, J.B. *Thin Solid Films* v 155 n 2 Dec 30 1987 p 331-342.

**094252 COMPARATIVE STUDY OF Ga(CH<sub>3</sub>)<sub>3</sub>, Ga(C<sub>2</sub>H<sub>5</sub>)<sub>3</sub> AND Ga(C<sub>4</sub>H<sub>9</sub>)<sub>3</sub> IN THE LOW PRESSURE MOCVD OF GaAs.** Our study presents data on the growth of GaAs obtained in a low pressure (10<sup>4</sup> Pa) metal organic chemical vapor deposition (MOCVD) system using Ga(CH<sub>3</sub>)<sub>3</sub> [TMG], Ga(C<sub>2</sub>H<sub>5</sub>)<sub>3</sub> [TEG] or Ga(C<sub>4</sub>H<sub>9</sub>)<sub>3</sub> [TIBG]. The growth efficiencies for these gallium sources, calculated on the basis of our own vapor pressure measurements, are of comparable magnitude. Due to the lower thermal stability of TEG and TIBG growth of GaAs is possible at lower temperatures. High quality films with free carrier concentration below 10<sup>15</sup> cm<sup>-3</sup> were grown at 923 K with TMG, at 843 K with TEG. The TIBG grown films tended to be n-type, probably due to contamination in the source. The electrical properties of the films are independent of the arsine overpressure (V/III ratio) in a broad range using TEG or TIBG. This allows epitaxial deposition of GaAs at a low consumption of AsH<sub>3</sub>. (Author abstract) 47 refs.

## Contacts

**094253 OHMIC CONTACTS ON p-TYPE Ga<sub>0.47</sub>In<sub>0.53</sub>As/InP.** Ohmic contacts of Au and Ag based Zn containing alloys on p-type Ga<sub>0.47</sub>In<sub>0.53</sub>As have been studied using intermediate layers of Ti and Ni, respectively. Low specific contact resistance in the order of 10<sup>-5</sup> Ωcm<sup>2</sup> are achieved. In AuZn alloy, the Ti intermediate metal layer causes higher contact resistances together with a worse contact morphology in contrast to Ni intermediate layers. However for AgZn contacts Ti adherent layers improve the contact resistances, especially for lower alloying temperatures. These contacts exhibit smoother interfaces as revealed by TEM micrographs. Thus AgZn contacts apply best to low resistive contacting of very thin p-layers forming e.g. the base of a ballistic device. (Edited author abstract) 11 refs.

## Crystal Lattices

**094256 LATTICE VIBRATIONS OF CuGaSe<sub>2</sub>, CuInSe<sub>2</sub> TERNARY COMPOUNDS, AND CuGa<sub>1-x</sub>In<sub>x</sub>Se<sub>2</sub> SOLID SOLUTIONS.** On the basis of IR reflection, transmission, and Raman spectra the frequencies of the vibrational modes of CuGaSe<sub>2</sub>, CuInSe<sub>2</sub>, and CuGa<sub>1-x</sub>In<sub>x</sub>Se<sub>2</sub> obtained and identified. It is shown that the lattice vibrations of the solid solutions display mixed type behavior. In the frequency range ω > 200 cm<sup>-1</sup>, the vibrational modes show two-mode behavior. Two relatively independent bands in this range are due to vibrations of Ga-Se atoms and In-Se, respectively, in antiphase. The vibrational modes in the low frequency range (ω > 200 cm<sup>-1</sup>) display one-mode behavior. (Author abstract) 7 refs.

## Defects

**094257 DISLOCATION STRUCTURE OF GaP CRYSTALS AFTER 6-10° BENDING.** More than one thousand individual dislocations have been examined by TEM in S-doped LEC-GaP after three-point bending of (001) wafers at temperatures in the range 605-615°C. A linear variation of dislocation density with bending angle between 6 and 10° is observed. The role of different dislocation types is investigated. An increasing proportion of 60° dislocations in {111} planes develops during bending. Macroscopic curvature is discussed in terms of the dislocation density observed. Resolved shear stresses are derived from slip-band observation. (Author abstract) 38 refs.

Pauffer, P. (Karl-Marx-Univ, Leipzig, East Ger); Rotsch, P.; Wagner, G. *Philos Mag A* v 56 n 4 Oct 1987 p 533-551.

**094258 ALLOY DISORDER BROADENING OF DEFECT ENERGY LEVELS.** The deep level transient spectroscopy (DLTS) peaks are broader in alloys than the peaks in binary III-V compounds. This effect is related to substitutional disorder present in the alloy which changes the sharp energy levels into a distribution. We give relations between the broadened DLTS signal, defect energy level broadening and alloys disorder with particular reference to electron irradiation induced E3 defect in GaAs<sub>1-x</sub>Sb<sub>x</sub> alloys. (Edited author abstract) 14 refs.

**094259 TRANSITION-METAL ELECTRON STATES IN IMPERFECT Ga<sub>2</sub>S<sub>3</sub> CRYSTALS.** Resonance techniques and, in particular, electron paramagnetic resonance (EPR) and γ-resonance (GR) are informative for the interpretation of the impurity character in defect semiconductors. These methods give information on the spatial distribution of paramagnetic ions, the chemical bond nature, and charge state of the atoms and their electronic structure. Ga<sub>2</sub>S<sub>3</sub> defect crystals were studied by EPR and GR within the 77 to 300 K range to determine the electronic states of Mn and Fe impurity atoms. The analysis reveals that electrically inactive Fe atoms are incorporated as Fe<sup>2+</sup> into the lattice and form chemical bonds with S atoms. 10 refs.

**094264 INTERACTION BETWEEN AN IMPURITY AND POINT DEFECT IN GaP AND GaAs CRYSTALS.** An analytical relation is established between the nonstoichiometry factor δ of a doped A<sup>III</sup>BV crystal and the equilibrium-liquids parameters of the crystal. The values of δ in the primary-crystallization range of GaP and GaAs are calculated along the equilibrium-liquidus isotherms in the Ga-P-Si, Ga-P-Zn, Ga-As-Si and Ga-As-Zn systems. It is shown that, qualitatively, the value of δ in highly doped GaP and GaAs crystals does not depend on the nature of the impurity or its state in the crystal. In Russian. 15 refs.

**094265 PRESSURE DEPENDENCE OF DONOR LEVELS IN GaP: ELECTRONIC RAMAN SCATTERING EXPERIMENTS.** Electronic Raman scattering experiments have been performed in S and Te doped GaP up to 47 kbar. We observe an increase of the energy of the 1S(T<sub>1</sub>)-1S(T<sub>12</sub>) interground state transition. Its pressure coefficient is very small and suggests that the

1S( $\Gamma_1$ ) donor ground state evaluate like a shallow level. The results are analyzed in terms of lattice parameter, screening, effective mass and umklapp parameter variations. (Author abstract) 28 refs.

Galtier, P. (CNRS, Grenoble, Fr); Martinez, G. *Solid State Commun* v 65 n 3 Jan 1988 p 193-197.

**094266 DEEP LEVELS IN NON-DOPED AND DONOR-DOPED GaP.** Four deep electron-rap levels were detected by DLTS from the non-doped and Te- or S-doped LEC-grown GaP. Some discussions are given regarding their origin. The density  $N_1$  of these levels increased linearly with the net donor density  $N_D$  for non-doped samples.  $N_1$  was reduced by doping Te with  $N_D$  approximately  $10^{17} \text{ cm}^{-3}$ , and then increased as  $N_D$   $10^{17}$  for  $N_D > 10^{17} \text{ cm}^{-3}$ . (Author abstract) 13 refs.

Endo, Tamio (Mie Univ, Tsu, Jpn); Uchida, Eiji; Hiro-saki, Yuushi; Sugiyama, Koichi. *Jpn J Appl Phys Part 1* v 27 n 1 Jan 1988 p 153-154.

**094267 CHARACTERIZATION OF DX CENTERS IN GaAlAs GROWN BY LIQUID-PHASE EPITAXY.** It is well known that n-type  $\text{Ga}_{1-x}\text{Al}_x$  solid solutions with  $x \geq 0.2$  doped with a group IV or VI element contain a large number of deep levels due to DX centers. This note reports on studies of p-n junctions prepared by growing an Sn-doped GaAlAs layer and a Ge- or Si-doped GaAs layer. The structures were grown for manufacturing of double heterostructure stripe geometry lasers. Two liquid phase epitaxial techniques were used for growing; the common sliding boat technique and a technique in which the solution used for the growth of the layer is pushed out by the solution for the subsequent layer. The p-n junctions were studied by measuring C-U and C-T characteristics, DLTS and DDLTS. 8 refs.

Zdansky, K. (Czechoslovak Acad of Sciences, Prague, Czech); Le Thanh, Binh. *Phys Status Solidi A* v 105 n 1 Jan 1988 p K51-K55.

**094268 INCORPORATION OF NITROGEN INTO GALLIUM ARSENIDE GROWN BY CHLORIDE VPE.** The incorporation of nitrogen into GaAs in the halide-VPE system using  $\text{NH}_3$  as the doping source is investigated. The concentration of incorporated N depends on the  $\text{NH}_3$  flow rate and increases with decreasing deposition temperature. Concentrations up to  $6 \times 10^{17} \text{ cm}^{-3}$  could be detected far above the calculated equilibrium value. By a comparison of SIMS-data with those obtained from IR it is found that most of the N-atoms are situated substitutionally on As lattice sites. Normal-pressure 2 K photoluminescence measurements show N-related luminescence peaks at 1.508 and 1.496 eV. Most probably this luminescence arises from complexes of N with undeliberately introduced impurities. For the 1.508 eV center a complex  $\text{Si}_{\text{Ga}}\text{-N}_{\text{As}}$  is discussed. (Edited author abstract) 13 refs.

## Electric Field Effects

**094272 ELECTRIC FIELD INDUCED REFLECTION IN GaInAsP/InP MQW STRUCTURE.** Reflection of light due to the electric field effect was seen for the first time in GaInAsP/InP MQW structures through the observation of an interference pattern between the transmitted and reflected light; this was caused by a change in the refractive index and absorption coefficient in the MQW layers due to the partial application of an electric field to the MQW layers. The observed data were fitted with the theoretical simulations and the refractive index change was predicted to be about 0.025% at  $-5 \text{ V}$ . This is a promising step towards the realization of the intersectional optical switch. (Author abstract) 10 refs.

**094280 EFFECT OF ELECTRON-PHONON COUPLING ON THE QUANTUM-CONFINED STARK EFFECT.** On the basis of intermediate-coupling scheme applied to the electron-phonon system in GaAs-GaAlAs quantum well structures we have calculated the electric field induced eigen-energy shift. A quadratic Stark shift is found at weak fields. For large enough electric fields the corrections due to the electron-phonon coupling are significant. (Author abstract) 8 refs.

Xu, Wang (Neimenggu Univ, Huhhot, China); Xi, Xia Liang; Kan, Chang. *Solid State Commun* v 65 n 1 Jan 1988 p 83-85.

**094281 TUNNELING OF ELECTRONS IN QUANTUM WELLS WITH INDIRECT GAP SEMICONDUCTOR BARRIERS.** One of the features peculiar to GaAs-Ga<sub>1-x</sub>Al<sub>x</sub> As quantum wells with  $x \geq 0.43$  are barriers formed by an indirect gap semiconductor. We make use of a simple one-dimensional tight-binding model to study the tunneling properties of such a system. Wave-functions and probabilities associated with an electron in each spatial region as a function of time are computed and compared with the results of a simple square barrier model. It is shown that the states related to the indirect conduction band minima of the barrier act as a new channel and increase the tunneling current between the wells. We suggest that these states are the origin of an unexplained structure observed in photoemission from a double quantum well. The effect of an external electric field is analyzed. **094284 OBSERVATION OF A GAP IN THE COUPLED INTERSUBBAND CYCLOTRON RESONANCE EXCITATIONS IN A QUASI TWO-DIMENSIONAL ELECTRON GAS.** Far-infrared magnetotransmission measurements are reported on the energies of the coupled intersubband-cyclotron resonance excitations in a GaAs-GaAlAs heterojunction in the presence of a large tilted magnetic field. It is experimentally found that the lowest lying coupled mode is pinned to an energy which is somewhat lower than the electric subband separation leading to an opening of a gap in the excitation energy spectrum. This is in qualitative agreement with a recent theoretical prediction. (Author abstract) 12 refs.

**094285 RESONANT DX CENTERS IN HIGHLY DOPED Sn-Ga<sub>1-x</sub>Al<sub>x</sub>As UNDER HYDROSTATIC PRESSURE IN A MAGNETIC FIELD.** We report

experimental evidence of deep impurity states producing a localized resonance in the  $\Gamma_{1c}$  band continuum in highly doped Sn-Ga<sub>1-x</sub>Al<sub>x</sub>As. At low temperatures and increasing pressure, electrons were transferred from the  $\Gamma_{1c}$  band to the deep Sn donor state; this transfer of carriers was directly related to the pressure dependence of Shubnikov de Haas oscillations. Persistent photoconductivity, due to the DX nature of this deep level, was observed through the increase in the  $\Gamma$  carrier density resulting from illumination with a light emitting diode. This is interpreted as a photoionization of the DX centers up to the  $\Gamma_{1c}$  valley. (Author abstract) 2 refs.

**094290 LASER-INDUCED THERMOCHEMICAL MASKLESS-ETCHING OF III-V COMPOUND SEMICONDUCTORS IN CHLORIDE GAS ATMO-**

SPHERE. Thermochemical maskless etching of compound semiconductors (GaAs, InP, InSb, and GaP) has been performed by focused Ar-laser irradiation in chloride gas atmospheres. A controlled minimum linewidth of down to  $0.6 \mu\text{m}$  with a maximum etching rate of up to  $13 \mu\text{m/s}$  has been obtained. Minimum laser powers necessary for thermochemical etching in each of compound semiconductors were found to be 0.24, 0.56, and 0.06 W, corresponding to minimum local temperatures rises of 190, 515, and  $110^\circ\text{C}$  for GaAs, InP, and InSb, respectively. Etching rates exhibited Arrhenius behavior with activation energies of 3.6-3.9 kcal/mole. Etching at excessively higher laser powers than those minimum powers was found, by microprobe photoluminescence measurements, to degrade the optical quality of the etched substrate. **094291 BERYLLIUM DIFFUSION ACROSS GaAs/(Al, Ga)As HETEROJUNCTIONS AND GaAs/AlAs SUPERLATTICES DURING MBE GROWTH.** Beryllium diffusion during MBE growth of (Al, Ga)As layers, (Al, Ga)As/GaAs heterojunctions and GaAs/AlAs superlattices has been studied by electrochemical C-V and secondary ion mass spectrometry (SIMS) concentration profiling, in conjunction with transmission electron microscopy. Diffusion times were comparatively short since they were limited to part of the growth sequence, so non-equilibrium effects had a significant influence. The results are consistent with an interstitial-substitutional mechanism in which lattice site incorporation becomes more difficult with increasing band gap enthalpy. Incorporation involves a 'kick-out' reaction which leads to the observed disordering of the superlattices. (Author abstract) 15 refs.

**094292 CRYSTAL GROWTH OF CuGaSe<sub>2</sub> FROM IN SOLUTIONS.** The phase relations of a CuGaSe<sub>2</sub>-In pseudobinary system have been studied and the conditions of preparation of the solid phase having the chalcopyrite crystal structure were obtained. On the basis of the data, CuGaSe<sub>2</sub> crystals were grown from In solutions, and their properties were examined. (Author abstract) 7 refs.

Sugiyama, Koichi (Mie Univ, Tsu, Jpn); Sawada, Atsushi; Ito, Koji; Iwasaki, Satoshi; Endo, Tamio. *J Cryst Growth* v 84 n 4 Oct 1987 p 673-675.

**094293 STUDY OF SUPERCOOLING BEHAVIOR OF InGaAsP SOLUTIONS FOR GROWTH OF HIGH QUALITY InGaAsP/InGaAs(P) LAYERS ON (100) InP.** The growth conditions for producing high quality InGaAsP ( $\lambda = 1.3 \mu\text{m}$ )/In<sub>0.53</sub>Ga<sub>0.47</sub>As interfaces on (100) oriented InP by liquid phase epitaxy were investigated in detail. Results on the variation of InGaAsP layer thickness, lattice mismatch and photoluminescence wavelength with growth temperature reveal that homogeneous nucleation of the quaternary growth melt occurs at a critical supercooling  $\Delta T_c$ . Four growth regimes,  $\Delta T > T_c$  and  $\Delta T < \Delta T_c$  in both the presence and absence of apparatus vibration were evaluated. High quality InGaAsP/InGaAs interfaces can be grown at melt cooling rates as low as  $0^\circ\text{C/min}$  for  $\Delta T < \Delta T_c$  in the absence of vibration, but vibration will slightly degrade interface quality. For  $\Delta T > \Delta T_c$ , melt cooling rates of approx.  $0.6^\circ\text{C/min}$  in the absence of apparatus vibration will yield

good interfaces; but melt cooling rates  $\leq 0.1^\circ\text{C}/\text{min}$  and/or apparatus vibration will result in very poor quality interfaces. (Edited author abstract) 16 refs.

**094294 THICKNESS CONTROL OF  $\text{Ga}_{1-x}\text{Al}_x\text{As}$  LAYERS GROWN BY LIQUID PHASE EPITAXY AT LOW GROWTH TEMPERATURE.** The uniformity of a  $\text{Ga}_{1-x}\text{Al}_x\text{As}$  layer grown by liquid phase epitaxy was investigated as a function of the growth temperature in the range of 600 to 800°C. Lowering the growth temperature causes the growth rate to decrease, which contributes to remarkable reductions in both the normalized edge growth height (H) and the thickness variation ( $\sigma$ ) over the wafer. At a growth temperature of 600°C, the flat  $\text{Ga}_{1-x}\text{Al}_x\text{As}$  (solid composition,  $x=0.45\pm 0.008$ ) layer of  $2.058\pm 0.07\text{ }\mu\text{m}$  ( $\sigma/d=3.4\%$ ) can be obtained with an edge growth height of  $2.92\text{ }\mu\text{m}$  ( $H=1.25$ ). On the other hand, at a short growth time of 0.3s, the variation of layer thickness of less than  $\pm 0.007\text{ }\mu\text{m}$  ( $\pm 8.9\%$ ) does not depend on the growth temperature. The probable lowest limit in a flat layer can be varied by the initial supersaturation. (Author abstract) 29 refs.

Todoroki, Satoru (Hitachi Ltd, Yokohama, Jpn); Ohbu, Isao; Kashiwada, Yasutoshi. *J Cryst Growth* v 85 n 3 Nov II 1987 p 461-468.

**094295 MODIFIED BRIDGMAN GROWTH AND ETCHING OF  $\text{Cd}_{0.96}\text{Zn}_{0.04}\text{Te}$  CRYSTALS.** A modified Bridgman technique, in which both the furnace and growth ampul are kept stationary, is used for the first time to grow single crystals of  $\text{Cd}_{0.96}\text{Zn}_{0.04}\text{Te}$ . Because of the stationary conditions, this method simplifies the conventional technique and minimizes vibrational disturbances which may interfere with the growth process. The Nagakawa etchant was found to produce etch pits on nonpolar (110) planes of  $\text{Cd}_{0.96}\text{Zn}_{0.04}\text{Te}$  crystals which are probably indicative of dislocations and the etch pit density was low. These observations, the very smooth cleavage planes, and well-defined Laue patterns show the single crystallinity of the material grown by this technique. 12 refs.

Trivedi, S.B. (Rensselaer Polytechnic Inst, Troy, NY, USA); Wiedemeier, H. *J Electrochem Soc* v 134 n 12 Dec 1987 p 3199-3201.

**094296 OMVPE OF  $\text{GaInAs}$  ON A SPINNING SUBSTRATE.** It is shown that thickness uniformity of OMVPE layers can strongly be improved by rotation of the substrate during growth. A new susceptor assembly to achieve rotation is presented. The new principle of supporting and driving a substrate holder without shafts and seals is shown to be capable of growing layers of  $\text{GaInAs}$  with a uniformity of layer thickness required for modern semiconductor devices. It should be possible to construct susceptor assemblies with this principle, that will handle wafers with 2 inch diameter or even larger. This susceptor could be used even in low pressure systems. (Edited author abstract) 8 refs.

**094297 MOLECULAR BEAM EPITAXY OF  $\text{GaAs}_x\text{P}_{1-x}$  USING LOW-ENERGY  $\text{P}^+$  ION BEAM.** We describe the epitaxial growth of  $\text{GaAs}_x\text{P}_{1-x}$  ( $0 < x < 0.7$ ) on  $\text{GaAs}(001)$  substrates using mass-separated low-energy  $\text{P}^+$  ions, and  $\text{Ga}$  and  $\text{As}_4$  molecular beams. Epilayers have been obtained at growth temperatures ( $T_g$ ) ranging from 300 to 650°C at  $\text{P}^+$  ion energies ( $E_{p+}$ ) between 50 and 300 eV. We have investigated the growth rate as a function of  $E_{p+}$  and the film composition as a function of the flux ratio of  $\text{As}_4$  to  $\text{P}^+$ ,  $T_g$ , and  $E_{p+}$ . The sticking coefficient of phosphorus is markedly enhanced by using  $\text{P}^+$  ion, compared with that of  $\text{As}_4$ . As the flux ratio of  $\text{As}_4$  to  $\text{P}^+$  is increased from 0 to 8, the composition ratio  $x$  of  $\text{GaAs}_x\text{P}_{1-x}$  complex  $\text{SiGa-NAs}_3$  is discussed. (Edited —  $x$  films varies from 0 to 0.5. The composition ratio  $x$  decreases slightly with increasing  $T_g$  from 400 to 650°C,

and increases with increasing  $E_{p+}$ . Film surfaces are smooth at  $E_{p+}$  below 100 eV, and their morphology is degraded with increasing energy. (Author abstract) 8 refs.

**094298 COMPOSITIONAL VARIATION RELATED TO THE GROWTH PROCESS IN  $\text{GaAlAs}$  EPITAXIAL LAYERS.** Compositional profiles of epitaxial  $\text{GaAlAs}$  layers grown by liquid phase epitaxy using the supersaturation technique were investigated in relation to the growth conditions by laser Raman spectroscopy. In the diffusion limited process with a flat temperature profile during epitaxial growth cycle, a uniform layer of  $1.26 \pm 0.017\text{ }\mu\text{m}$  ( $\pm 1.3\%$ ) with a small compositional variation of  $0.457 \pm 0.007$  ( $\pm 1.5\%$ ) can be accomplished. On the other hand, remarkable compositional variations ( $> \pm 10\%$ ) occur during an initial growth stage, which depends on the initial supersaturation. Compositional uniformity is improved to  $0.152 \pm 0.007$  ( $\pm 4.6\%$ ) by decreasing initial supersaturation to 2.5°C. (Author abstract) 26 refs.

**094301 GROWTH BY ANTIPHASE-DOMAIN-FREE  $\text{GaP}$  ON  $\text{Si}$  BY ORGANOMETALLIC VAPOR PHASE EPITAXY.** Heteroepitaxial growth of  $\text{GaP}$  on  $\text{Si}(100)$  substrates organometallic vapor phase epitaxy (OMVPE) is studied. The effects of substrate pretreatment procedures on antiphase-domain-free  $\text{GaP}$  film growth are also investigated. These procedures include final chemical treatment just before loading into an OMVPE reactor and increased preheating temperature just before growth. By optimizing these pretreatment procedures, antiphase-domain-free  $\text{GaP}$  films are successfully grown on nominally just-cut (100) substrates as well as (100) substrates with a  $4^\circ$  tilt toward [011] by optimizing these pretreatment procedures. A photoelectrochemical etching procedure is demonstrated as a new, convenient method for revealing antiphase domain (APD) structures in grown films. Advantages of the two-step growth method for obtaining  $\text{GaP}$  films with good surface morphology are also discussed. (Author abstract) 11 refs.

**094303 NEW APPROACH FOR DETERMINING THE LIQUIDUS AND SOLIDUS ISOTHERMS OF THE SYSTEMS  $\text{A}^{\text{III}}\text{-B}^{\text{III}}\text{-CV}$ .** Compounds of the type  $\text{A}^{\text{III}}\text{-B}^{\text{III}}\text{-CV}$  have found widespread application in the industrial production of different semiconductor devices. The phase diagrams of the systems they are realized from are the basis for the controllable synthesis of those compounds. The analytical relationships of the liquidus and solidus isotherms for the  $\text{A}^{\text{III}}\text{-B}^{\text{III}}\text{-CV}$  systems are represented in this article. They are compared with theoretical and experimental results which different authors have obtained for the  $\text{Ga-Al-As}$ ,  $\text{Ga-Al-P}$ ,  $\text{In-Ga-As}$  and  $\text{In-Ga-P}$  systems. The relationships obtained correspond very well with the results. (Author abstract) 14 refs.

Nedev, N.K. (Inst of Micro & Optoelectronics, Botevgrad, Bulg); Minkov, D.A. *J Cryst Growth* v 88 n 4 May II 1988 p 429-434.

**094304 OMVPE GROWTH OF UNIFORM  $\text{Ga}_{1-x}\text{In}_x\text{As}$ .** Because of its optical and electrical characteristics,  $\text{Ga}_{1-x}\text{In}_x\text{As}$  ( $x=0.53$ ) lattice-matched to  $\text{InP}$  is one of the most promising materials for the fabrication of such devices as high-speed transistors, light-receiving and light-emitting devices which operate in the wavelengths from 1.3 to 1.55- $\mu\text{m}$  used in long-wavelength optical transmission, and the optoelectronic ICs in which these discrete devices are used. As a thin-film epitaxial growth method for this  $\text{Ga}_{1-x}\text{In}_x\text{As}$ , Sumitomo Electric has introduced organometallic vapor phase epitaxy (OMVPE). By making improvements in existing technology, the authors have succeeded in developing OMVPE technology capable of growing, with excellent reproducibility,  $\text{Ga}_{1-x}\text{In}_x\text{As}$  thin films with a uniform alloy compositional distribution on a two-inch  $\text{InP}$  substrate. It was also confirmed through double-crystal x-ray diffractometry and photoluminescence measurements that the grown  $\text{Ga}_{1-x}\text{In}_x\text{As}$  thin film has excellent crystal quality. (Edited author abstract) 7 refs.

**094305 MASS SPECTROMETRIC STUDY OF THE REACTION OF TRIETHYLINDIUM WITH ARSINE GAS.** A study of the premature room temperature gas-phase reactions involved in the growth of  $\text{GaInAs}$  using  $\text{Et}_3\text{In}$ ,  $\text{Me}_3\text{Ga}$ , and  $\text{AsH}_3$  was undertaken, using a specially designed mass spectrometer sampling system on a conventional, low pressure OMVPE (Organometallic Vapor Phase Epitaxy) reactor. It was shown that the reaction of the  $\text{Et}_3\text{In-AsH}_3$  mixture could be described by reversible bimolecular reaction kinetics within the limits of experimental error, and evidence for an adduct is presented. The equilibrium constant for this system was determined as 30 torr; the rates of forward and reverse reaction were  $5\text{ (torr-s)}^{-1}$  and  $0.15\text{ s}^{-1}$ , respectively. The implications of the reaction of this organometallic source with arsine on the growth mechanism is discussed. (Edited author abstract) 28 refs.

**094307 KINETIC ASPECTS OF ORDERING IN  $GaAs_{1-x}Sb_x$  GROWN BY ORGANOMETALLIC VAPOR PHASE EPITAXY.** Long range ordered structures have been studied in  $GaAs_{1-x}Sb_x$  alloys with  $x \approx 0.5$  grown by organometallic vapor phase epitaxy (OMVPE). The emphasis of this paper is on the kinetic effects leading to the occurrence of ordering. In particular, the effects of growth temperature, growth rate, and substrate orientation are reported. The ordered simple tetragonal CuAu-I ( $L1_0$ ) and the chalcopyrite ( $E1_1$ ) structures were observed at the highest growth temperatures from 580 to 660°C on (100) oriented InP substrates with both high and low growth rates. We also examined samples grown on (221) and (311) oriented InP substrates at 550°C. They showed very little ordering with only local observation of weak  $L1_0$  superlattice electron diffraction spots. (Edited author abstract) 33 refs.

**094310 ELECTRON PARAMAGNETIC RESONANCE OF TITANIUM IN GaP.** EPR and photo-EPR experiments are reported performed on LEC-grown GaP:Ti with different Fermi-level positions. An isotropic signal with  $g=1.952$  and a linewidth of 20.0 mT is assigned. An acceptor level is located at  $(0.5 \pm 0.1)$  eV below the conduction band minimum. (Edited author

abstract) 17 refs.

**094312 HOLE TRAPS IN GaSe:Co SINGLE CRYSTALS.** In order to clarify the nature of the cobalt related hole traps (CRHT) in GaSe single crystals, GaSe:Co single crystals were grown by the Bridgman method and the optical absorption spectra, the photoconductivity spectra and the thermally stimulated current (TSC) were investigated. The energy levels of the CRHT in GaSe:Co single crystals were located at 0.18, 0.28, 0.38, 0.49 and 0.57 eV above the valence band. The optical absorption peaks and the photoconductivity peaks corresponding to the CRHT were observed in the wavelength range from 650 to 950 nm and these peaks are respectively attributed to the carrier transitions from the CRHT to the indirect conduction band of GaSe:Co single crystals. (Author abstract) 6 refs.

**094313 NITROGEN BOUND ELECTRONS, EXCITONS, AND MULTIEXCITONS IN GaP.** By means of a simple effective mass model the density functional theory is used to calculate the ground state energy of the exciton at the isolated N impurity. For this purpose, the N potential is adjusted and provides the value known from experiment. This potential offers the basis for the computations of the bound multiexciton complexes at the isolated N impurity and of the electron binding energy at the N pairs. The results so obtained are in good qualitative agreement with the experimental ones. (Author abstract) 21 refs.

Haufe, A. (Karl-Marx-Univ Leipzig, Leipzig, East Ger). *Phys Status Solidi B* v 144 n 2 Dec 1987 p 733-738.

**094314 RAMAN SCATTERING STUDY OF GaP:IN EPITAXIAL LAYERS.** Raman spectra of VPE-grown GaP:In samples were investigated in the temperature range between 20 and 300 K, using five discrete lines of the Ar-ion laser. The nitrogen concentration ranged from  $2 \times 10^{17}$  to  $3.3 \times 10^{19} \text{ cm}^{-3}$ . Four nitrogen-related peaks were observed. While the origin of the high-frequency peak is unclear at present, the arguments are given to identify the remaining peaks with a defect-activated LO(X) mode, a nitrogen local vibrational mode, and with its first overtone, respectively. (Author abstract). 33 Refs.

Matter, Proc of the Int Conf on Lumin, Beijing, China, Aug 17-21 1987 p 417-418.

**094316 QUANTUM WELLS AND DEEP IMPURITY LEVELS UNDER HYDROSTATIC PRESSURE.** We present a cryogenic temperature study of confined transitions and deep impurity levels in a  $GaAs-Ga_{1-x}Al_xAs$  multiple quantum well under hydrostatic pressure. Photorefectance at 80 to 300K was used to study quantized states up to  $n=7$ . A sublinear pressure behavior was found, with pressure coefficients that decreased with increasing n. Indirect transitions from L and X conduction bands were observed. Photoluminescence at 18K was used to observe a deep level, and its phonon replica, that is resonant below 24 and above 80kbar. The level is observed both in bulk GaAs and the quantum well, and may be due to Si impurities. (Edited author abstract) 21 refs.

## Ion Implantation

**094317 EFFECT OF HYDROGEN IMPLANTATION INDUCED STRESS ON GaP SINGLE CRYSTALS.** The fluence dependence of internal stress, of plastic deformation and of flaking are studied on GaP single crystals bombarded with 0.1-1.7 MeV protons at 300 and 650 K and annealed at 720 K in the range of fluences  $D=10^{15}$  to  $10^{18} \text{ cm}^{-2}$  using photoelastic stress measurements, cross sectional transmission electron microscopy, scanning electron microscopy and profilometry. It is demonstrated that the implanted hydrogen precipitates in planar form at higher concentrations. The proton bombarded region consists of a less damaged near-surface layer and of a highly damaged 'buried' layer. Within the 'buried' layer supersaturated with point-like defects thermal annealing makes simpler defects coagulate to Frank loops. At the interface between the implanted layer and the bulk material microcracks are formed due to lateral stresses. Stress increases with fluence and exhibits saturation behavior due to plastic deformations which lead to flaking at very high stresses. (Author abstract) 39 refs.

Ascheron, C. (Karl-Marx-Univ Leipzig, Leipzig, East Ger); Bartsch, H.; Setzer, A.; Schindler, A.; Paufler, P. *Nucl Instrum Methods Phys Res Sect B* v B28 n 3 Oct 1987 p 350-359.

**094318 DOPANT REDISTRIBUTION AND CRYSTALLINE DAMAGE REMOVAL DURING RAPID THERMAL ANNEALING OF Be AND Mg IMPLANTS IN  $Ga_{0.47}In_{0.53}As$ .** Secondary ion mass spectrometry (SIMS) and 1.5 MeV Rutherford backscattering (RBS) have been used to correlate redistribution of Be<sup>+</sup> and Mg<sup>+</sup> implants with the reordering of damaged crystal during rapid thermal annealing (RTA) of  $Ga_{0.47}In_{0.53}As$ . Studies were made of three different implant conditions:  $1 \times 10^{14} \text{ cm}^{-2}$  Be<sup>+</sup> and  $1 \times 10^{15} \text{ cm}^{-2}$  Mg<sup>+</sup>, implanted at room temperature, and also  $1 \times 10^{14} \text{ cm}^{-2}$  Mg<sup>+</sup> implanted at 200°C. In addition, a comparison was made of two different methods of surface protection, CVD Si<sub>3</sub>N<sub>4</sub> and a GaAsP 'proximity cap'. It is found that redistribution of Be<sup>+</sup> differs slightly for the two types of surface protection employed, but that the use of RTA suppresses excessive indiffusion effects observed during long time furnace anneals. It is proposed that regrowth in GaInAs occurs in a similar manner to that observed in GaAs and InP. Proximity annealing results in retention of all the implanted Mg<sup>+</sup> dose. (Edited author abstract) 25 refs.

**094319 ANNEALING BEHAVIOUR OF EXTREMELY LOW ENERGY BERYLLIUM IMPLANTATION INTO  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As}$ .** Low energy ion implantation (2-10 keV) of beryllium has been performed and annealing carried out by rapid thermal annealing at different temperatures. Secondary ion mass spectrometry measurements of implanted profiles showed a strong diffusion of the beryllium atoms towards the surface. For the lowest implantation energies this influence is so strong that no indiffusion could be measured. The resulting annealed profile is much narrower than the implanted profile. From diodes fabricated from these layers, a barrier enhancement of 0.42 eV has been determined. (Author abstract) 10 refs.

Fernholz, G. (RWTH, Aachen, West Ger); Breuer, U.; Beneking, H. *Thin Solid Films* v 156 n 2 Jan 30 1988 p 239-242.

**094320 PHOTOLUMINESCENCE STUDIES OF Mg AND Hg IMPLANTED  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As}$ .** Mg and Hg have been implanted in  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As}$ . These impurities behave as shallow acceptors in  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As}$ . Hg is particularly interesting because it does not diffuse towards the bulk. From systematic photoluminescence measurements as a function of excitation power, ion dose and temperature, the Mg and Hg acceptor binding energy are estimated to be, respectively,  $16 \pm 2$  and  $68 \pm \text{meV}$ . (Edited author abstract) 15 refs.

**094321 GETTERING OF COPPER IN PROTON-AND HELIUM-BOMBARDED BURIED REGIONS OF GALLIUM PHOSPHIDE.** The effect of copper gettering was studied in buried damaged regions caused by proton ion implantation of 300 and 600 keV, respectively. During annealing procedures copper atoms implanted with 200 keV redistribute from the surface layer into buried damaged regions. It is demonstrated that this gettering procedure can be advantageous over the commonly used back side ion beam gettering. (Author abstract) 17 refs.

Ascheron, C. (Karl-Marx-Univ Leipzig, Leipzig, East Ger); Klose, H.A.; Frentrup, W.; Griepentrog, M. *Phys Status Solidi A* v 106 n 1 Mar 1988 p 73-79.

## Magnetic Field Effects

**094322 MAGNETO-OPTICAL TRANSITIONS IN GALLIUM PHOSPHIDE.** The structure of the magnetic levels of the GaP valence band has been calculated within the framework of the effective-mass method. We have determined the effective masses of holes in the direction of a field parallel to [001], the probabilities of magneto-optical transitions, and their dependence on the reduced wave vector. The distinctive features of the magneto-optical spectra of GaP are discussed. 6 refs.

**094323 HALL EFFECT STUDIES ON p-TYPE GaSb GROWN UNDER MICROGRAVITY CONDITIONS.** Undoped GaSb crystals are always p-type with hole concentration of about  $1 \times 10^{17} \text{ cm}^{-3}$  and Hall mobility of 600 to 800  $\text{cm}^2/\text{Vs}$  at room temperature. The residual acceptor responsible for this behavior is thought to be associated with lattice defects arising from deviations from stoichiometry, the lattice defect being probably a Ga vacancy and a Ga atom on a Sb lattice site. This note presents the results of Hall effect analysis of residual acceptors in a crystal grown under microgravity conditions and a control sample grown on earth. Hall data were measured between 300 and 20 K. The concentrations of both acceptors and donors are greater in the terrestrial samples than in the crystal grown under microgravity conditions. In accordance with the lower impurity concentrations and compensation degree, the Hall mobility at 77 K is higher in the crystal grown under microgravity

conditions. 22 refs.

## Measurements

**094324 ELECTROREFLECTANCE AND PHOTOREFLECTANCE MEASUREMENTS OF GAAS/ALAS SHORT PERIOD SUPERLATTICES.** Electroreflectance and photorefectance measurements are reported for GaAs/AlAs short-period superlattice over the wavelength range 9000/3000 Å. Emphasis is on the spectral region of 4500-3000 Å where the observed structures have been associated with the  $E_1$  and  $E_1 + \Delta_1$  transitions of the superlattice. These transitions are shifted toward higher energies when the well-width decreases. The experimental results are compared with a simple calculation based on a Kronig-Penney model. (Edited author abstract). 10 refs.

**094328 OPTICAL INVESTIGATIONS OF A GaSb-ALSB SINGLE QUANTUM WELL.** We present a study of the low temperature electroreflectance and photoluminescence of GaSb-ALSB single quantum well heterostructure grown by molecular beam epitaxy. Our results evidence the important role of misfit strains in the electronic structure of this system. The luminescence, which is remarkably intense, arises from excitons bound to shallow defects which are most likely neutral acceptors. (Author abstract) 12 refs.

Raisin, C. (Univ des Sciences et Techniques du Languedoc, Montpellier, Fr); Lassabaterre, L.; Allibert, C.; Girault, B.; Abdel-Fattah, G.; Yoisin, P. *Solid State Commun* v 61 n 1 Jan 1987 p 17-19.

**094329 ANALYSIS OF THE EXCITONIC MOTT TRANSITION IN GaSe.** Detailed photoluminescence spectra of GaSe at a bath temperature of 2K were measured at electron-hole densities ranging from below to above the screening limit for the free direct excitons. Special care was used to reduce the effects of spatial carrier inhomogeneity. We observe a continuous transition from exciton recombination processes to an e-h plasma emission. We compare our observations with the results of a simplified first order theory which accounts for electron-hole correlation effects. The observed red shift of the fundamental direct exciton level is well reproduced by our theoretical calculations. (Author abstract) 21 refs.

**094330 USING DISPERSION THEORY TO INTERPRET THE POLARIZATION PROPERTIES OF THE BAND-EDGE EMISSION IN GaN CRYSTALS.** In this paper, we report the polarization properties of the near band-edge emission in GaN crystal wafers. When excitation intensity increases in the range of 0-0.1  $\text{Mw cm}^{-2}$ , the polarization of band-edge emissions increase quadratically, then, a saturation appears. These phenomena can be explained by the dispersion theory of exciton-exciton interaction. (Author abstract) 6 refs.

Bao, Qincheng. (Chinese Acad of Sciences, Changchun, China); Zhang, Fengling; Li, Duolu; Dai, Rensong; Xu, Xurong. *Solid State Commun* v 61 n 6 Feb 1987 p 381-384.

**094331 MAGNETO-OPTICAL STUDIES OF  $\text{GaInAs-InP}$  QUANTUM WELLS.** The optical properties of GaInAs-InP quantum wells are studied in magnetic fields of up to 16T. A comparison of the absorption and photoluminescence spectra of a series of multiple quantum wells provides evidence that the photoluminescence occurs from excitons in which the hole is localised. This localisation is shown to be present in a highly doped sample with a sheet carrier density of approximately  $10^{12} \text{ cm}^{-2}$ , indicating that the localisation is not screened out by high free carrier densities. A theoretical fit to measured Landau level transitions in a 100 Å multiple quantum well allows values for the carrier masses, electron non-parabolicity and exciton binding energy to be determined. (Author abstract) 21 refs.

## Order-Disorder

**094334 DISORDER OF A  $Ga_{1-x}In_xAs_{1-y}P_y$  INP QUANTUM WELL BY Zn DIFFUSION.** Data are presented showing for the first time that Zn diffusion into a  $Ga_{1-x}In_xAs_{1-y}P_y$  INP quantum well and superlattice (of 100 Å thickness) completely disorders the quantum well and superlattice layers. The photoluminescence wavelength of the quantum well and the superlattice increased after Zn diffusion, which can be attributed to the In-Ga interdiffusion at the hetero-interfaces, as a result of the interchange mechanism between the interstitials and substitutional zinc atoms. (Author abstract) 15 refs.

Razeghi, M. (Thomson-CSF, Orsay, Fr); Acher, O.; Launay, F. *Semicond Sci Technol* v 2 n 12 Dec 1987 p 793-796.

**094335 ORDERED STRUCTURE IN OMVPE-GROWTH  $Ga_{0.5}In_{0.5}P$ .** The ordered structure of Ga and In in GaInP grown on (00) GaAs by organometallic vapor phase (OMVPE) is investigated using high-resolution transmission electron microscopy (TEM). The orderings are sequences of (111) planes arranged in the order of Ga/P/In/P/Ga/P/InP along the [111] and  $\bar{1}\bar{1}\bar{1}$  directions, respectively. The ordered structure may be thermodynamically stable. The OMVPE growth mechanism may partly determine ordering direction in the crystal. (Edited author abstract) 8 refs.

## Oxidation

**094336 LONG-TIME AIR OXIDATION AND OXIDE-SUBSTRATE REACTIONS ON GaSb, GaAs AND GaP AT ROOM TEMPERATURE STUDIED BY X-RAY PHOTOELECTRON SPECTROSCOPY.** The room temperature oxidation behaviour of GaSb, GaAs and GaP has been monitored for a period of 3 years using X-ray photoelectron spectroscopy. By comparisons of the compositions of the growing oxide and the depth profiles of the 3-year oxide, information on the oxide-substrate interfacial reactions is obtained. The growing oxide surface consists of  $Ga_2O_3$  and  $Sb_2O_3$  (Sb:Ga  $\approx$  1) for GaSb, a metastable Ga-O-As complex (As:Ga  $\approx$  0.5) for GaAs, and  $P_2O_5$  and  $Ga_2O_3$  +  $GaPO_4$  (P:Ga  $\approx$  3) for GaP. The oxide-substrate reaction occurs for GaSb and GaAs, and the resulting interface shows three features: (1) increase in gallium oxide; (2) decrease in the  $B^V$  oxide; (3) deposition of elemental B<sup>v</sup>, even at room temperature, although a very long period of time is necessary. For GaP, no such reaction occurs. (Edited author abstract) 32 refs.

**094339 SINGLE-HETEROJUNCTION GaAlAs - A NEW TECHNOLOGY FOR INFRARED LEDs AND OPTOCOUPLERS.** This technology, originally developed to provide brighter hyper-red LEDs, offers a significant improvement over rival GaAs and GaAlAs homojunction technology for infrared emitters. Advantages include higher operating speed, better reliability, linear radiant intensity/forward-current relation and a higher radiant intensity where needed. (Edited author abstract)

Boissy, Marie Claude. *Electron Compon Appl* v 8 n 3 1988 p 153-155.

**Photoconductivity** See Also ELECTRODES, ELECTROCHEMICAL—Semiconductor Materials.

**094340 WAVELENGTH-DEPENDENT PHOTOCONDUCTION EFFECTS ON THE SECOND SUB-BAND OCCUPANCY IN (Al, Ga)As/GaAs HETEROJUNCTIONS.** We have used magneto-transport measurements with the magnetic field aligned perpendicular to, and then parallel to the interface of a number of (Al, Ga)As/GaAs two-dimensional electron-gas samples, to determine the populations of the first and second sub-bands in the interface potential well. The total carrier density in the samples has been gradually increased by pulsed illumination either with a red ( $h\nu=1.95$  eV) or infrared ( $h\nu=1.43$  eV) LED, and it has been found that the carrier density at which the second sub-band is first occupied is lower when the red LED is used. This difference is ascribed to the effect of electron-hole pairs generated in the GaAs altering the depletion charge, and hence the sub-band spacing; such a mechanism does not operate when the infrared LED is used. (Edited author abstract) 14 refs.

## Physical Properties

**094341 INVESTIGATION OF PROPERTIES OF THE GALLIUM PHOSPHIDE/INSULATOR INTERFACE.** The special physicochemical properties of III-V semiconductors are such that thermal oxidation cannot be used when building up the elements of opto- and microelectronics, and low-temperature processes must be

found to form insulating films. A highly promising method of this kind is anodic oxidation in electrolytes. Research workers have shown considerable interest in semiconductor/insulator interfaces of structures on the basis of GaAs and InP, but only a few papers have been concerned with systems consisting of GaP and an anodic oxide film (AOF). (Edited author abstract) 6 refs.

**094343 BAND LINEUPS AT THE  $GaSb-Al_xGa_{1-x}Sb$  HETEROJUNCTION: EXPERIMENTAL EVIDENCE FOR A NEW COMMON ANION RULE.** The valence band offset in  $GaSb-Al_xGa_{1-x}Sb$  quantum wells has been determined by a light scattering method and found to be nearly the same as in their  $GaAs-Al_xGa_{1-x}As$  counterparts. This result suggests the validity of a restricted form of the common anion rule, which can be stated as follows: the valence band offset in a common anion heterostructure tends to be independent of the particular anion chosen. This new rule is consistent with Tersoff's band lineup theory and also with a recent tight binding theory by Harrison and Tersoff. (Author abstract) 27 refs.

## Plasmas

**094345 OPTICAL GAIN SPECTRA OF HIGH DENSITY ELECTRON-HOLE PLASMA IN GaSe AND InSe.** We have performed stimulated emission and unsaturated optical gain measurements at low temperature in the indirect semiconductors GaSe and InSe at excitation intensities above 0.5 MW/cm<sup>2</sup>, i.e., when the critical Mott density is overcome and an electron-hole plasma (EHP) is generated. In both GaSe and InSe the gain spectra show only the band due to zero phonon recombination of indirect plasma (IEHP). No optical gain due to direct plasma (DEHP) is observed. The comparison of experimental results with theoretical models is very satisfactory. In InSe it becomes also a tool for evaluating the consistence of proposed band structures with observed

data. (Author abstract) 16 refs.

## Precipitation

**094346 PRECIPITATE IDENTIFICATION IN LEC-GROWN SI-DOPED GaAs.** It is shown that the phase which precipitates due to normal segregation in LEC-grown Si-doped GaAs, once the solid solubility of the dopant is exceeded, is elemental Si. The presence of high Si concentrations in the melt also promotes the formation of a further precipitate which appears at the melt-encapsulant interface and also becomes incorporated into the crystal surface. This precipitate has been identified as  $B_{13}As_2$ . (Author abstract) 13 refs.

## Pressure Effects

**094347 HYDROSTATIC PRESSURE EFFECTS ON Mn IN GaAs<sub>1-x</sub>P<sub>x</sub>.** Hydrostatic pressure has been applied to samples of Mn-doped GaAs and GaAs<sub>1-x</sub>P<sub>x</sub> ( $x = 0.04$ ). The charge transfer nature of the radiative recombination allows determination of the pressure derivative of the Mn acceptor level relative to the valence band edge. The pressure derivatives have been determined and are found to be identical for both the binary and ternary material, 1.1-1.2 meV/kbar. This number is only a small fraction of the total pressure derivative of the  $\Gamma_{1c}$   $\Gamma_{15v}$  energy gap which amounts to 10.7 meV/kbar. Using the Mn acceptor energy level as a reference we were able to determine the hydrostatic deformation potentials of the valence and conduction bands and found values of  $a_v = +0.9$  eV and  $a_c = -7.7$  eV respectively. (Edited author abstract) 24 refs.

## Radiation Effects

**094348 USING GaAs AND GaP FILMS WITH ABNORMAL PHOTOVOLTAGES FOR RECORDING X-RAYS.** The possibility of recording x-rays with films made for CdTe and Sb<sub>2</sub>Se<sub>3</sub> semiconductor compounds which upon illumination with visible light generate an abnormal photovoltage has been reported. These films are sensitive to x-rays only in air, whereas their sensitivity disappears in vacuum. This behavior is associated with the increase in the ion concentration in air where the films can be shunted by ion currents or by the interaction of ions with the surface of the films. It has also been shown that it is possible to use Si and Ge films with an abnormal photovoltage for recording x-rays in both air and vacuum. The author considers in the present work the possible application of films made from  $A_3B_5$  semiconductor compounds (GaAs and GaP) with an abnormal photovoltage for recording x-rays. 5 refs.

**094349 ELECTRICAL PROPERTIES AND FERMI LEVEL PINNING IN PROTON-IRRADIATED GaSb.** The effect of electron, fast neutron, and deuteron irradiations on the electrical properties of GaSb has been previously investigated. These irradiations convert n-type GaSb to p-type and shift the Fermi level into the lower half of the energy gap. The authors describe the effect of proton (5 MeV) bombardment on the electrical properties and Fermi level positions of the initial n-, p-, and p<sup>+</sup>-type bulk GaSb. The samples were irradiated using a cyclotron with current densities from  $(0.5 \text{ to } 5) \times 10^{-4} \text{ A/cm}^2$ . 6 refs.

## Spectroscopic Analysis

**094353 INFLUENCE OF THE JAHN-TELLER EFFECT UPON ZERO-PHONON LINES IN OPTICAL SPECTRA.** A mechanism involving the Jahn-Teller effect is used to account for both strong and absent zero-phonon lines in optical spectra. The method is applied to explain why the 1.03 eV zero-phonon line of the GaP:Cr<sup>3+</sup> system is very strong, while no zero-phonon line is observed from the GaAs:Cr<sup>3+</sup> system. (Author abstract) 15 refs.

Dunn, J.L. (Univ Nottingham, Nottingham, Engl); Bates, C.A. *J Phys C Solid State Phys* v 20 n 36 Dec 30 1987 p L995-L998.

**094354 TIME-RESOLVED EXCITON PHOTOLUMINESCENCE IN GaSe AND GaTe.** Time-resolved photoluminescence measurements of the layered semiconductors GaSe and GaTe have been made using a mode-locked dye laser and a synchronously scanning streak camera. It is shown that at low excitation densities ( $10^{15}$ ,  $10^{17} \text{ cm}^{-3}$ ) exciton dynamics is dominated by trapping at defects. A rate equation model is developed that describes exciton formation, recombination and trapping. At 4 K we determine free-exciton recombination times of 200 ps for GaTe and 350 ps for GaSe. Trapping times of 200 and 900 ps yield capture cross sections of  $1.2 \times 10^{-14} \text{ cm}^2$  and  $3.6 \times 10^{-15} \text{ cm}^2$  for GaTe and GaSe respectively. (Author abstract) 17 refs.

**094355 POSSIBILITY OF A DIRECT OBSERVATION OF THE TIME EVOLUTION IN HETEROSTRUCTURE BARRIER TUNNELING.** By varying two design parameters, e.g., the width of a quantum well (QW) and its chemical composition, or by applying an external field, it is possible to implement two QW's with identical ground-state levels in the conduction band - but different in the valence band. This allows a selective 'preparation' of an initial electron state by interband photoexcitation. In a coupled QW system the electron will oscillate between the two wells, giving rise to an oscillating luminescence signal with a period directly related to the tunneling time. (Author abstract) 8 refs.

Luryi, Serge (AT&T, Murray Hill, NJ, USA). *Solid State Commun* v 65 n 8 Feb 1988 p 787-789.

**094356 LUMINESCENCE DECAY OF EXCITONS BOUND TO NITROGEN PAIRS IN GaP:N.** We report photoluminescence lifetime studies of excitons bound to  $NN_1$  and  $NN_3$  pair centres in GaP:N in the temperature range of 4.5-110 K. The experimental results show that the temperature dependence of the luminescence lifetime of  $NN_3$  centres is not very different from sample to sample, while that of  $NN_1$  centres is quite different for different sample. For  $T > 40 \text{ K}$ , in a sample with very small electron-escape probability of the bare electron state, it is observed that thermal release of the hole from  $NN_1$  center, and verifies the Hopfield-Thomas-Lynch (HLT) model of isoelectronic traps. (Author abstract) 11 refs.

**094358 SPECTROSCOPIC STUDIES OF THE LOCAL SYMMETRY OF NITROGEN PAIRS IN GaP.** We presented an investigation of the defect symmetry associated with nitrogen-nitrogen pairs in GaP. We only found defects associated with  $C_{2v}$  or  $C_s$  local-symmetry groups [(a, a, 0) or (a, a, b) orientations of two substitutional atoms]. This contradicts the standard assignment. Performing a model calculation which takes account of the conduction band structure of GaP. We show that specific features indeed exist in indirect band gap semiconductors. They prevent a simple assignment in terms of nitrogen-nitrogen separation. The change in exciton binding energy arises from the microscopic arrangement around the nitrogen atom. This is illustrated from hydrostatic pressure and uniaxial stress measurements; it also permits an analysis of the nitrogen related isoelectronic complexes found in the alloys. (Author abstract) 46 refs.

#### Structure See Also SEMICONDUCTING ZINC COMPOUNDS—Structure.

**094369 ELECTRONIC STRUCTURE OF TERNARY SEMICONDUCTOR ALLOYS: CPA CALCULATIONS USING  $\text{sp}^3\text{s}^*$  BANDSTRUCTURES.** Coherent potential approximation (CPA) calculations of the electronic structure of the III-V ternary alloys  $\text{GaAs}_{1-x}\text{P}_x$ ,  $\text{Ga}_x\text{In}_{1-x}\text{As}$ ,  $\text{Ga}_{1-x}\text{Al}_x\text{As}$ ,  $\text{Ga}_x\text{In}_{1-x}\text{P}$ , and  $\text{GaSb}_{1-x}\text{P}_x$  are reported. Results are presented for the CPA self-energies, state densities, and band-bowing functions for these materials. The calculations utilize the  $\text{sp}^3\text{s}^*$  bandstructures as input into the Chen and Sher CPA formalism. The present work is the first utilization of these bandstructures in CPA calculations for ternary alloys and the first CPA treatment of  $\text{GaSb}_{1-x}\text{P}_x$ . In qualitative agreement with previous studies, the results of these

calculations show that alloy disorder effects are small for  $\text{GaAs}_{1-x}\text{P}_x$ , of moderate importance for  $\text{Ga}_x\text{In}_{1-x}\text{As}$  and  $\text{Ga}_x\text{Al}_{1-x}\text{As}$ , and relatively large for  $\text{Ga}_x\text{In}_{1-x}\text{P}$ . (Edited author abstract) 23 refs.

**094370 POLARITY DETERMINATION IN  $\langle 111 \rangle$ -ORIENTED GaSb BY HIGH-RESOLUTION TRANSMISSION ELECTRON MICROSCOPY AT 300 kV.** The polarity of orientations of  $\langle 110 \rangle$  projected single crystals of tetrahedral compound semiconductors has been determined by high-resolution electron microscopy (HREM) at 300 kV. The method has been applied to GaSb and computer simulations show that the image contrast is the reverse of that expected intuitively. Similar results are predicted for GaAs. (Author abstract) 5 refs.

Wright, A.C. (Univ of Manchester Inst of Science & Technology, Manchester, Engl); Ng, T.L.; Williams, J.O. *Phil Mag Lett* v 57 n 2 Feb 1988 p 107-111.

**094371 TEMPERATURE DEPENDENCE OF  $X_1$ - $X_3$  SPLITTING ENERGY IN LIGHTLY DOPED GaP.** The splitting energy  $\delta$  between the  $X_1$ -band with an effective mass  $m_1^*$  and the  $X_3$ -band with  $m_2^*$ , and the effective mass ratio  $m_2^*/m_1^*$  for the conduction band on n-GaP were determined as a function of the temperature T by measuring the infrared absorption and fitting theoretical curves of the  $X_1 \rightarrow X_3$  absorption band. As T rises,  $\delta$  decreases as  $0.349 \cdot 6.83 \times 10^{-5} T^2 / (T + 460) [\text{eV}]$ , which can be explained by a faster shift of the upper  $X_3$ -band than the lower  $X_1$ -band toward the valence band. This empirical equation gives  $\delta = 316 \text{ eV}$  at 773 K. The  $m_2^*/m_1^*$  increases, which indicates that the upward-bending of the  $X_1$ -band has a stronger T-dependence than the  $X_3$  band. (Author abstract) 22 refs.

**094372 CRYSTAL STRUCTURE OF  $\text{Ga}_2\text{Se}_{3-3x}\text{Te}_3$ .** Up to now, the quaternary system  $\text{Ga}_2\text{Se}_{3-3x}\text{Te}_3$  has been considered as completely miscible in the solid state. Nevertheless, Woolley and Smith concluded from the nonlinear dependence of the cubic lattice constant on the concentration parameter x that there should be an ordered compound in the vicinity of  $x = 0.25$ . The authors reinvestigated the system  $\text{Ga}_2\text{Se}_{3-3x}\text{Te}_3$  in this concentration region by means of X-ray powder diffraction and microprobe analysis. Samples were prepared either by sintering of powder mixtures of  $\text{Ga}_2\text{Te}_3$  and  $\text{Ga}_2\text{Se}_3$  at elevated temperatures or by reaction between a  $\text{Ga}_2\text{Se}_3$  crystal and a  $\text{Ga}_2\text{Te}_3$ -rich gas phase at 1000 K. The diffuse zinc-blende pattern does not transform to a sharp one, but to the new pattern of the tetragonal lattice. 4 refs.

**094376 INTERACTION BETWEEN TWO SURFACE EXCITATIONS IN DEGENERATE POLAR SEMICONDUCTORS.** A systematic study of the interaction of surface plasmons with surface optical phonons is made for III-V group polar semiconductors, namely, GaSb, InSb, GaAs, InAs, GaP, and InP, to find the factors which can influence the coupling between the two modes of vibrations. It is found that the extent of coupling depends upon the Szegedi effective charge or the ionicity of the compound. (Edited author abstract) 17 refs.

**094377 PROPRIETES ELECTRONIQUES DES SURFACES DE GaSb ET AISb PREPAREES PAR EXPITAXIE PAR JETS MOLECULAIRES.** [Surface Electronic Properties of GaSb and AISb Prepared by Molecular Beam Epitaxy]. This paper deals with MBE grown GaSb and AISb (100) surfaces. After a brief description of the growth conditions, the authors detail some results obtained by EELS (primary electron energy 100 eV - 500 eV) and discuss the modifications of the spectra induced by oxygen adsorption and by annealing. (Author abstract) 3 refs. In French.

Da Silva, F.W.O. (CNRS, Montpellier, Fr); Raisin, C.; Lassabatre, L. *Vide Couches Minces* v 43 n 241 Mar-Apr 1988, 2emes Journ Etud sur L'Epitaxie et la Passivation des Composés III - V, Fr, Apr 27-28 1988 p 233-234.

**094378 ETUDE DES SURFACES DE GaSb PAR LA METHODE D'ETUDE EN SPECTROSCOPIE DE PERTES D'ENERGIE DES ELECTRONS LENTS ENTRE 293 K ET 523 K.** [Study of GaSb Surfaces by Electron Energy Loss Spectroscopy Between 293 K and 523 K]. Results obtained on UHV (110) GaSb cleaved surfaces by electron energy loss spectroscopy (EELS) and the Kelvin method in the 293-523 K temperature range are given. At 293 K the comparison between EELS spectra from freshly and oxidized cleaved surfaces reveals deep modifications of the loss structures relative to the 5-10 eV energy range and to the surface exciton. When increasing temperature on freshly cleaved n and p-type GaSb surfaces, their work functions begin to rise at 320 K. At the same time, on freshly cleaved surfaces the loss structure from Sb-4d gets a better defined doublet at 32.5

and 33.7 eV. This structure vanishes at higher temperatures and begins to reappear around 500 K. (Author abstract) 4 refs. In French.

## Switching

**094379 IMPEDANCE SWITCHING EFFECTS IN GaAs/AlAs BARRIER STRUCTURES.** AlAs tunnel barriers in MBE-grown GaAs layers have been studied using pulsed and continuous I/V and swept temperature/capacitance measurements. Such layers demonstrate an impedance switching phenomenon which is persistent and repeatable. This impedance switching is manifested by the device as two distinct impedance modes: a high-impedance mode (of the order of 10 k $\Omega$  at dc for a 0.3 mm dot), and a low-impedance mode (of the order of 10  $\Omega$ ). Such a phenomenon may restrict the operation of some devices, but may lead to other novel applications. (Author abstract) 3 refs.

## Thermodynamic Properties

**094380 LATTICE VIBRATION AND THERMODYNAMICAL PROPERTIES OF ZINC-BLENDE TYPE SEMICONDUCTOR COMPOUND (GAP).** A six parameter non-central dynamic model for zinc blende compounds is developed which takes into account the covalent nature of atomic bonds. It is considered that during rotation, angles between bonds remain the same and only energy changes due to rotation of valence bonds formed by overlap of hybrid directional wave functions of neighbouring atoms. The dispersion curves, specific heat and Debye characteristic temperatures of GaP are calculated and compared with experimental data. The agreement is satisfactory. (Edited author abstract) 26 refs.

**094381 THERMODYNAMIC ANALYSIS OF THE CuGaSe<sub>2</sub>-In SYSTEM.** Liquidus and solidus curves have been calculated for the CuGaSe<sub>2</sub>-In system by assuming CuGa<sub>x</sub>In<sub>1-x</sub>Se<sub>2</sub> chalcopyrite or Ga<sub>x</sub>In<sub>1-y</sub>Se<sub>2</sub> layer structure alloys as the solid phases. We use the liquidus interaction parameters derived from solubility parameters, molar volumes and electronegativities of elements, whereas the solidus interaction parameters are taken as adjustable parameters for fitting to the experimental data. The obtained results indicate that the calculated liquidus points for In solutions containing high concentrations of CuGaSe<sub>2</sub> solute correspond to the CuGa<sub>x</sub>In<sub>1-x</sub>Se<sub>2</sub> solid phase and are fitted fairly well to the experimental data, and that the Ga<sub>x</sub>In<sub>1-y</sub>Se<sub>2</sub> is stable as the solid phase associated with liquid solutions containing lower concentrations of CuGaSe<sub>2</sub>. (Author abstract). 17 Refs.

**094382 DOUBLE CRYSTAL X-RAY ROCKING CURVES OF MULTIPLE LAYER STRUCTURES.** Interference effects in double crystal x-ray rocking curves arising from the existence of a sub-micrometer layer sandwiched between two layers of different composition

are studied by simulation and experiment. For GaInAs structures on InP with a quarter micrometer middle layer, composition and thickness could be determined to an accuracy of 50 ppm and 50 Å respectively. There is an excellent consistency between interference structures and layer parameters deduced from various reflections. The sensitivity of the interference structures to other layer parameter variations is investigated. (Author abstract) 16 refs.

Chu, X. (Univ of Durham, Durham, Engl); Tanner, B.K. *Semicond Sci Technol* v 2 n 12 Dec 1987 p 765-771.

**094383 DETERMINATION DU PROFIL DE CONCENTRATION DE LA COUCHE DE TRANSITION DE HETEROSTRUCTURES Ga<sub>1-x</sub>Al<sub>x</sub>As/GaAs PAR RENDEMENT DE PHOTOEMISSION X.** [Determination of the Concentration Profile for the Transition Layer in Ga<sub>1-x</sub>Al<sub>x</sub>As/GaAs by X-Ray Photoemission]. The experimental measurement of X-ray photoemission jumps is carried out for Ga<sub>1-x</sub>Al<sub>x</sub>As/GaAs epitaxial heterostructures where a superficial thin film is first corroded by various chemical treatments. Assessment of the composition profile of the GaAlAs-GaAs interface region is realized by the non-destructive X-ray photoemission jump method. It shows that the results obtained are compatible with the characteristics of photocurrent spectra. (Author abstract) In French. 12 refs.

**094385 CHEMICAL MODIFICATION OF GaP-CI THIN FILM PHOTOELECTRODES.** Modification of chlorogallium phthalocyanine (GaPc-CI) thin film photoelectrodes with thin films of polyvinylferrocene (PVF), thin films of PVF with incorporated ferricyanide, and thin films of a coprecipitated ferricinium-ferricyanide salt is demonstrated. The analysis of the coprecipitated ferricinium-ferricyanide salt demonstrates the formation of a Prussian Blue (PB)-like electroactive film. PVF films on bare gold were first characterized to demonstrate incorporation of ferricyanide during formation of ferricinium ions. This was followed by demonstration of the direct interaction of ferrocenium and ferricyanide, without the polymer, on bare gold, and on the Pc surface. GaPc-CI films overlaid with PB thin films formed from ferrocenium/ferricyanide can produce either negative or positive photopotentials, depending upon the dopant condition of the Pc layer, relying only upon the photoelectrochemical redox activity of the PB layer. (Edited author abstract). 23 Refs.

**094386 RAMAN SCATTERING FROM PERIODIC AND NONPERIODIC GaSb/AISb STRAINED-LAYER LATTICES.** Raman scattering measurements have been performed on a series of periodic and nonperiodic strained-layer GaSb/AISb lattices. In the optical frequency region quantum confined longitudinal optic phonons are observed in GaSb layers when the layer width

is less than 25 Angstrom. Spatially extended interface modes lying within the LO-TO regions for both GaSb and AlSb are also seen. The interface mode frequencies are not well fit by current macroscopic theories. The confinement-induced  $\Gamma$ -to-L crossover in GaSb manifests itself via the observation of a scattering structure which resembles the optical phonon density of states. In structures grown with supercell or nonperiodic symmetry, the acoustic spectra display zone folding as well as nominally forbidden modes whose frequencies lie close to but are not exactly coincident with zone boundary phonons. Acoustic phonons in a quasiperiodic Fibonacci lattice have been measured and compared to periodic rational approximant lattices with (ABAAB) or (ABAABAAB) repeat units. (Author abstract) 36 refs.

**094388 TUNNELING STUDIES OF THE MINIBAND STRUCTURE OF A SUPERLATTICE.** It is now known that electron transport in narrow barrier superlattices proceeds by miniband conduction. However, previous experiments have been limited to studying electrons in the bottom of the first miniband. We report tunneling measurements which have enabled us to inject electrons into any position in the superlattice miniband structure. The MBE grown GaAs/(AlGa) As samples consist of an electron injector, an AlGaAs tunnel barrier and a superlattice. By biasing the structure we are able to control the electron injection energy, and the corresponding tunnel current shows pronounced negative differential resistance associated with the presence of minibands and band gaps. Analysis of the I-V characteristic shows that Bloch transport and not sequential tunneling is occurring. (Author abstract) 8 refs.

## Vapor Deposition

**094389 REACTIONS OF TRIETHYLINDIUM AND TRIMETHYLGALLIUM WITH ARSINE GAS.** A study of the premature room temperature gas-phase reactions involved in the growth of GaInAs using  $\text{Et}_3\text{In}$ ,  $\text{Me}_3\text{Ga}$  and  $\text{AsH}_3$  was undertaken, using a specially designed mass spectrometer sampling system on a conventional, low pressure organometallic vapor phase epitaxy reactor. It was shown that the reaction of the  $\text{Et}_3\text{In-AsH}_3$  mixture could be described by reversible bimolecular reaction kinetics within the limits of experimental error, and evidence for an adduct is presented. The equilibrium constant for this system was determined as 30 Torr; the

rates of forward and reverse reactions were  $5 \text{ (Torr s)}^{-1}$  and  $0.17 \text{ s}^{-1}$  respectively. The  $\text{Me}_3\text{Ga-AsH}_3$  reaction was found to occur at room temperature in less than 0.2 s; as a result, only lower bounds for the equilibrium constant and the rate of forward reaction could be determined. 11 refs.

**Amorphous** See Also SEMICONDUCTING SILICON—Amorphous; SEMICONDUCTING SILICON—Magnetic Properties.

**094391 EXAFS OF DISORDERED SYSTEMS.** EXAFS is a new tool for structure determination of materials. It complements the standard diffraction techniques and opens up new possibilities for systems not amenable to other methods. In an application to amorphous Ge, EXAFS showed that its structure is a continuous random network and not a microcrystalline state. However, in transforming to the crystalline state amorphous Ge was found to pass through a mixed amorphous-microcrystalline state. The crystallization is a continuous transition extending over a  $T_g$  range of at least 70°C. Even at the highest  $T_g$  of 370°C the sample has not fully crystallized. EXAFS was able to discern the distinction between the microcrystalline and amorphous states because of high resolution due to its capability to detect data to higher k-values than diffuse x-ray scattering. This high resolution also led to a more accurate characterization of the first coordination shell relative to the crystalline state. 7 refs.

**094392 PHOTO-INDUCED EFFECTS IN AMORPHOUS Ge-S.** The authors report the results of experiments on light induced ESR (LESER), photoluminescence and photodarkening in Ge-S films. From these results, they propose a model to explain the present and previous results. In this model, all the defect centers have negative-U, but they have a broad distribution of the activation energy for recovery from  $D^0$  to  $D^+$  and  $D^-$ . An interesting point in this model is that the value of the activation energy changes by illumination and annealing reversibly because of the structural change surrounding the defect. Such a structural change is probably related to the photodarkening. An inducing rate of  $D^0$  by illumination is assumed to be correlated with the activation energy of the defect center. The present model is in contrast to the suggestion by Biegelsen and Street that prolonged illumination introduces additional defects, which have a relation with the photo-darkening. 13 refs.

**094394 STRUCTURE AND EXISTENCE OF THE FIRST SHARP DIFFRACTION PEAK IN AMORPHOUS GERMANIUM PREPARED IN UHV AND MEASURED IN-SITU.** The structure of 'glassy' germanium films prepared by slow sublimation of germanium on heated substrates in ultra-high vacuum was investigated using in-situ high-energy transmission electron elastic scattering. It is shown that on the basis of the presently available experimental evidence, there exists a number of important physical constraints as to the structure of amorphous germanium. Furthermore, a diffraction pre-peak has been observed, the first such observation in tetrahedrally bonded elemental amorphous semiconductor. This result is discussed in the light of similar observations in other disordered systems. The significance of short- and medium-range real space correlations in disordered systems is pointed out. (Edited author abstract) 35 refs.

Viscor, Petr (Roskilde Univ Cent, Roskilde, Den). *J Non Cryst Solids* v 101 n 2-3 May 1988 p 156-169.

**094395 INFLUENCE OF BOND-ANGLE AND DIHEDRAL-ANGLE DISORDERS ON THE TOP OF THE VALENCE BAND OF AMORPHOUS GERMANIUM.** The electronic structure of amorphous germanium (a-Ge) is considered using a tight-binding scheme with all first-neighbor couplings in a continuous random network. The dihedral-angle and bond-angle disorders are found to be important at the valence-band-edge and responsible for the observed features near the top of the valence band. At the top of the valence band of a-Ge a tail of localized states  $\approx 0.4 \text{ eV}$  in width is found. (Author abstract) 24 Refs.

**Applications** See SEMICONDUCTOR COUNTERS—Performance.

## Calculations

**094396 MICROSCOPIC CALCULATION OF THE LATTICE DYNAMICS OF GERMANIUM USING PSEUDO-ATOMS.** The phonon frequencies of germanium are calculated using a quantum-mechanical dynamical matrix and the pseudo-atom expression for the change in charge density. A model pseudo-atom is constructed from Phillips' bond charge model with the dimensions of the bond charge taken from the static crystal: each pseudo-atom moves rigidly with its ion and is taken to consist of a central part and half of each adjacent bond charge. Without exchange-correlation (XC) effects, the calculated phonon spectrum is unsatisfactory with several acoustic modes being unstable. Several modifications of the model are tried but do not rectify this. An expression for the energy contribution caused by the SC effects is derived using perturbation theory. The implications of the treatment of the XC effects is discussed and so are some possible improvements to the model pseudo-atom. (Author abstract) 26 refs.

**094399 GENERATION OF HOT CARRIERS IN A SEMICONDUCTOR ROD WITH A NOTCH.** The current transport mechanism of the SOGICON-type Ge device is studied. Current-voltage characteristics were measured by applying pulsed voltage. As the voltage was increased, there appeared first a sublinear region in the current-voltage characteristics, and then current oscillation. From the present experiments, it was verified that the appearance of the sublinear region is ascribed to the generation of the hot carriers. (Author abstract) 3 refs.

Kamigaki, Tetsuya (Tokai Univ, Hiratuka, Jpn); Choe, Il Yong; Akiba, Yukio; Kurosu, Tateki; Iida, Masamori. *Jpn J Appl Phys Part 1* v 27 n 4 Apr 1988 p 692–693.

**094400 EXTRINSIC SELF-TRAPPING AND NEGATIVE U OF OXYGEN-RELATED THERMAL DONORS IN GERMANIUM.** The occurrence of some types of configurationally bistable thermal donors with negative effective correlation energy ( $U < 0$ ), that are formed at initial stages of heat treatment at  $T \leq 673\text{ K}$  of the oxygen containing germanium crystals is presented. The study of the equilibrium electron occupation containing germanium crystals is presented. The study of the equilibrium electron occupation function of three transforming thermal donors types enables one to obtain the values of  $U$  and the probability of double electron occupancy. By means of the kinetics of thermal donor transformation processes between two equilibrium configurations the activation energy and the cross-section for extrinsic self-trapping of charge carriers are determined. The results obtained are discussed in terms of very large lattice relaxation phenomena. (Author abstract). 23 Refs.

Litvinov, V.V. (Byelorussian State Univ, Minsk, USSR); Palchik, G.V.; Urenev, V.I. *Phys Status Solidi A* v 108 n 1 Jul 1988 p 311–321.

### Chemical Vapor Deposition

**094401 VAPORIZATION OF GERMANIUM DIOSIDE.** Germanium dioxide vaporizes decomposing as  $\text{GeCl}_4(\text{g})$  and germanium metal. We have found it useful to study this system and to measure a set of pressures by the Knudsen and torsion effusion methods. This letter summarizes, for each run, the vapor pressure-temperature equations calculated by least-squares treatment of the results. 14 refs.

Piacente, Vincenzo (Univ 'La Sapienza', Rome, Italy);

Stranges, Stefano; Scardala, Paolo. *J Mater Sci Lett* v 6 n 8 Aug 1987 p 972–974.

**094402 GROWTH AND ETCHING OF GERMANIUM FILMS BY CHEMICAL VAPOR DEPOSITION IN A  $\text{GeCl}_4\text{--H}_2$  GAS SYSTEM.** The etching and growth of germanium films are investigated using a  $\text{GeCl}_4\text{--H}_2$  gas system in the temperature range of  $490\text{--}565^\circ\text{C}$ . At relatively low  $\text{GeCl}_4$  partial pressures less than  $2 \times 10^{-3}$  torr, epitaxial growth of Ge is observed on Ge (100) surfaces, whereas at  $\text{GeCl}_4$  partial pressures higher than  $2 \times 10^{-3}$  torr, etching of the Ge film is found to occur. In the experiments utilizing patterned substrates, where the surface consists of defined areas of Ge and  $\text{SiO}_2$ , Ge is found to deposit selectively only on the exposed Ge regions. The growth reactions of Ge epitaxial films proceed through the Langmuir-Hinshelwood mechanism: the surface reaction takes place between two hydrogen atoms dissociatively adsorbed and a surface-adsorbed  $\text{GeCl}_2$  molecule. (Edited author abstract) 18 refs.

Ishii, Hiromu (NTT, Atsugi, Jpn); Takahashi, Yasuo. *J Electrochem Soc* v 135 n 6 Jun 1988 p 1539–1543.

**094403 FORMATION OF AMORPHOUS SEMICONDUCTORS BY CHEMICAL VAPOUR DEPOSITION FROM ORGANOGERMANIUM COMPOUNDS.** Attention is focused on chemical vapor deposition (CVD) from organometallics (OM) to produce (by a process known as OM-CVD) amorphous, thin-layer semiconductors from organogermanium compounds. Deposits from thermolyses of precursors (diluted  $1:10^4$  with helium) at atmospheric pressure in a quartz tube are collected on wafers of monocrystalline silicon, silica or alumina set on a heated graphite plate, and gaseous products are analyzed. Thermal stabilities decrease, and the compounds decompose at lower temperatures ( $150\text{--}200^\circ\text{C}$ ) than do the corresponding organosilicon compounds. Thermolysis mechanisms, deduced from gaseous products, are consistent with the presence of germynes as intermediates. The most thermolabile compounds decompose cleanly to form amorphous and homogeneous layers. Optical gaps, deduced from absorption spectra, are between 0.8 and 1.50 eV. (Edited author abstract) 27 refs.

Mazerolles, P. (Univ Paul Sabatier, Toulouse, Fr); Moranchio, R.; Reynes, A. *Silicon Germanium Tin Lead Compd* v 9 n 2–3 1986, Fifth Int Conf on the Organometall and Coord Chem of Germanium, Tin and Lead, Padua, Italy, Sep 7–11 1986 p 155–183.

### Contamination

**094404 THERMODYNAMICS OF THE REACTION BETWEEN A GERMANIUM MELT AND QUARTZ GLASS.** The results of a thermodynamic calculation show that reduction of quartz glass may be the cause of its contaminating action during contact with a germanium melt. In the  $1300\text{--}1900\text{ K}$  range the main components of the vapor phase above the germanium melt/quartz glass system should be germanium monoxide, germanium and silicon monoxide. The silicon content in the germanium is determined by the oxygen partial pressure above the system, an increase in which should cause a decrease in the silicon content in the melt. 11 refs. In Russian.

Devyatich, G.G.; Krasnova, S.G.; Pronchatov, A.N. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 6 Jun 1987 p 1027–1030.

### Crystallization

**094405 INFLUENCE OF THE INTERFACE ON THE CRYSTALLIZATION OF AMORPHOUS GE IN PD/GE MULTILAYERS.** The amorphous to crystalline phase transition of Ge in contact with Pb has been extensively investigated in Pb/Ge multilayers. We find that the Ge crystallizes at reduced temperatures in the range of  $100\text{--}200^\circ\text{C}$  depending on the thickness of the Ge and the Pb. Simultaneously the texture of the Pb improves and the layered structure completely disappears. It is suggested that the basis for the reduction of the crystallization temperature is the enhanced diffusion kinetics at

the interface, caused by the adjacent Pb layer. (Author abstract). 21 refs.

### Defects

**094406 STACKING-FAULT ENERGIES IN SEMICONDUCTORS FROM FIRST-PRINCIPLES CALCULATIONS.** A procedure to calculate stacking-fault energies in semiconductors from first principles without the need to perform large supercell calculations is proposed. This procedure is applied to calculate the energies of extrinsic and intrinsic stacking faults in germanium and silicon carbide using recently published total-energy calculations as input. The sign of the extrinsic-stacking-fault energy is proposed as an indicator for the occurrence of polytypism, in accordance with a recently proposed explanation of polytypism based on an ANNNI model. (Author abstract) 13 refs.

Denteneer, P.J.H. (Eindhoven Univ of Technology, Eindhoven, Neth); van Haeringen, W. *J Phys C Solid State Phys* v 20 n 32 Nov 20 1987 p L883–L887.

**094407 INVESTIGATION OF DISLOCATION MOBILITIES IN GERMANIUM IN THE LOW-TEMPERATURE RANGE BY IN SITU STRAINING EXPERIMENTS.** The mobility of screw and  $60^\circ$  dislocations in thin, single-crystal foils of germanium has been studied by in situ tensile testing in a high-voltage electron microscope operating at 400 kV, at stresses around 40 MPa and temperatures around  $400^\circ\text{C}$ . The velocity of the dislocations was found to depend strongly on their length, and this is discussed in terms of a double-kink mechanism with a high lattice friction on kinks. Activation energies for kink formation and migration are deduced from fits of the velocity-length curves, and discussed in terms of core structures of partial dislocations. (Author abstract) 19 refs.

**094408 ATOMIC STRUCTURES AND ELECTRON SPECTRAL OF (110) SMALL-ANGLE BOUNDARIES IN GERMANIUM BICRYSTALS.** An examination of the dislocation's structure and electronic parameters of small-angle boundaries can elucidate some features of the excitation structure and spectrum for the electron subsystem and can enable one to extrapolate the results to not excessively small inclination angle, including ones allowing of quasi-two-dimensional conductivity. One can examine DLTS spectra associated with these boundaries in n-type germanium bicrystals. The DLTS spectrum was measured by applying a regular train of voltage pulses, with the charge at the boundary relaxing in the intervals between pulses towards the equilibrium value on account of thermal ejection for electrons trapped during the pulses. The changes in level population at the boundary were determined by measuring the nonequilibrium capacitance and resistance. In both cases, the measured DLTS spectra were identical. 10 refs.

### Deformation

**094409 MAGNETISM OF PLASTICALLY DEFORMED Ge AND Si CRYSTALS.** Susceptibility  $\chi$  of plastically deformed Ge and Si single crystals was investigated. The plastic deformation leads to the appearance of dependence  $\chi$  on the magnetic field value and then to the decrease of Ge and Si single crystals diamagnetism. The peculiarities of the behavior are interpreted on the basis of the suggested ferromagnetic properties of dislocations. (Author abstract) 9 refs.

Kiev, USSR); Shakhovtsov, V.I.; Shindich, V.L.; Shpinar, L.I.; Shubak, M.I.; Stym, V.S.; Yaskovets, I.I. *Solid State Commun* v 63 n 1 Jul 1987 p 1-3.

## Density

**094410 IN-SITU MEASUREMENTS OF THE DENSITY OF AMORPHOUS GERMANIUM PREPARED IN ULTRA-HIGH VACUUM.** A non-destructive, in-situ technique has been used to determine the density of amorphous germanium films, prepared in ultra-high vacuum by slow sublimation onto heated single crystal sapphire substrates. Contrary to previous results, a density deficit with respect to the crystal has been observed. It is pointed out that the density deficit with respect to the crystalline phase (where such exists) is a general feature common to all bulk glasses and that it should be considered also as a characteristic structural feature of a stable state of amorphous germanium. The apparent thickness dependence of the measured density is discussed in terms of a single relaxation mechanism. (Author abstract) 14 refs.

## Doping See Also CRYSTALS—Growing.

**094411 BERYLLIUM-HYDROGEN AND ZINC-HYDROGEN SHALLOW ACCEPTOR COMPLEXES IN GERMANIUM.** New shallow acceptor complexes with hydrogenically-spaced excited states have been discovered in intentionally-doped crystals of otherwise ultra-pure germanium. The doping consists of  $> 10^{14}$  cm $^{-3}$  of group II impurities, and the crystal were grown under hydrogen atmosphere. The identification proposed is that of a hydrogen-group II impurity complex, with piezospectroscopic behavior of a  $\langle 111 \rangle$ -oriented defect. (Edited author abstract) 24 refs.

## Electric Properties

**094414 SPATIO-TEMPORAL INSTABILITIES IN THE ELECTRIC BREAKDOWN OF p-GERMANIUM.** Investigating the impact-ionization-induced avalanche breakdown in homogeneously doped p-germanium samples cooled to liquid-helium temperatures, we observed the spontaneous formation of current oscillations and current filaments in a highly nonlinear regime of the current-voltage characteristic. The spontaneous current

oscillations exhibit typical nonlinear dynamics as different routes to chaos under small variation of a control parameter. Self-organized emergence of quasiperiodic and mode-locked states can be ascribed to the simultaneous presence of two and more competing fundamental oscillatory modes intrinsic to our semiconductor system. Due to the coupling of the corresponding localized oscillation centers, typical nonlinear phenomena known from the circle-map formalism can be observed. We report on the spatially resolved observation of current filament patterns developing during avalanche breakdown. Two-dimensional imaging of the nucleation and the dynamics of the current filaments has been obtained by low-temperature scanning electron microscopy. These self-generated spatial structures are closely linked to the nonlinear shape of the current-voltage characteristic. Combining spatially and time-resolved measurements enables the localization of the temporal current instabilities in the boundary region of the current filaments. (Edited author abstract) 12 refs.

## Electronic Properties

**094416 STUDIES ON THE ELECTRONIC ENERGY STATES OF GERMANIUM MICROCRYSTAL AND THE CHEMICAL SHIFT DUE TO SURFACE OXIDIZATION BY MEANS OF PHOTOELECTRON SPECTROSCOPY.** The energies of electronic states in the germanium microcrystals which were made by evaporation in inert gas (He) at low pressure were deduced from the photoelectron spectra induced by X-ray and ultraviolet irradiations. The valence band structure of the microcrystal which has the size ca. 4 nm in diameter was similar to that of the amorphous state. The origin may be due to a change in the many-body effect, an interaction between a hole and an electron, and/or multi-scattering of an electron originating in the imperfection in the structure of a microcrystal. The energies of inner-core electrons of a microcrystal which has size ca. 4 nm were the same as that of the bulk. The chemical shift due to oxidation of a powder-like microcrystal differs from that of the bulk surface. (Author abstract) 6 refs.

**094417 QUANTUM LIMIT CYCLOTRON RESONANCE IN Ge - ACOUSTIC DEFORMATION POTENTIAL SCATTERING.** Electron cyclotron resonance linewidth in pure Ge has been studied for acoustic deformation potential scattering in the quantum limit. The relaxation time derived therefrom is obtained as a function of temperature (10 to 160 K) and magnetic field (17 to 75 kG). The inverse relaxation time for acoustic deformation potential scattering in the quantum limit is found to be proportional to temperature and to the square root of the magnetic field. These experimental results are explained qualitatively by Meyer's prediction. (Author abstract) 25 refs.

## 094418 INELASTIC SCATTERING TIME OF

**ELECTRONS IN METALLIC Ge:Sb.** We measured the negative magnetoresistance in Ge:Sb at low temperatures, and derived the inelastic scattering time applying the localization theory. The inelastic scattering time shows, above liquid He temperatures,  $T^{-3/2}$  dependence which is due to the electron-electron interaction in a dirty medium. Below about 1 K temperature the dependence is weaker. It is not explained by the spin scattering independent of temperature, and indicates the inelastic scattering time or the spin scattering having weak temperature variation. (Author abstract) 14 refs.

## Etching

**094422 CHEMICAL ETCHING OF GERMANIUM.** Epitaxial germanium is an important material for the fabrication of tandem solar cells and long wavelength photodetectors. The polishing of germanium substrates, prior to germanium epitaxy, is thus an important step. A series of etching experiments have been conducted to evaluate chemical etches for this approach. It is found that the most satisfactory surfaces are obtained with a 2-3 min treatment in  $\text{HNO}_3:\text{CH}_3\text{COOH}:\text{H}_2\text{O}$  in an 18:8:5 ratio by volume. (Author abstract) 7 Refs.

## Grain Boundaries

**094423 CHARACTERIZATION OF POLYCRYSTALLINE GERMANIUM BY EBIC.** The electron-beam-induced-current (EBIC) mode of a scanning electron microscope has been used to characterize the electrical activity of the grain boundaries in germanium. The boundaries have been characterized from a structural point of view using electron channeling patterns (ECP) and X-ray topography. The low-angle boundaries in Ge polycrystals show an EBIC contrast  $C$  which increases when the beam energy increases, while the  $\Sigma 3$  twins do not show a significant activity even when there is a deviation from the coincidence orientation. The collection efficiency of  $\eta$  of Schottky contacts has been measured. Both  $C$  and  $\eta$  measurements cannot be quantitatively analyzed using previously existing models. The basic ideas which should lead to a better modeling are discussed. (Author abstract) 20 refs.

## Ion Implantation

**094427 EFFECT OF  $\text{N}_2^+$ -ION IMPLANTATION ON ELECTRONIC PROPERTIES OF AMORPHOUS Ge.** The effect of introduction of large number of defects on the electrical properties of a-Ge film has been studied. Deposits of a-Ge of thickness 2000 Angstrom were obtained by evaporating 99.99% pure germanium from an Mo boat on to clean glass substrates with pre-deposited Al electrodes. After low temperature dc conductivity measurements, the samples were bombarded with  $\text{N}_2^+$  ions of 30 and 45 keV energy at room temperature and conductivity measurements repeated for bombarded films. The slopes of the plots of  $\ln \sigma_{dc}$  versus  $T^{-1/4}$  indicate that the density of localized states increase

considerably on ion implantation but return to the values before ion implantation on annealing at  $100^\circ\text{C}$  for 30 min, indicating the process of creation of defects is reversible. (Author abstract) 1 ref.

## Ionization

**094428 ORIENTATION DEPENDENT SURFACE DIPOLE AND FERMI-LEVEL POSITION ON A CLEAN Ge CYLINDER.** Photoelectron spectroscopy was used to measure the orientation-dependent photoionization threshold  $\xi$  ( $\alpha$ ) and Fermi-level pinning position ( $E_v - E_F$ ) at the surface. A cylindrically shaped Ge sample was prepared to allow in situ investigations. The comparison between Ge, Si, GaAs and W data confirms that relaxation-induced dipoles determine  $\xi$  ( $\alpha$ ) on nonpolar semiconductors. The variation of the pinning position shows distinct features. (Edited author abstract) 11 refs.

Kuhr, H.J. (Max-Planck-Gesellschaft, Berlin, West Ger); Ranke, W. *Solid State Commun* v 61 n 5 Feb 1987 p 285-287.

## Low Temperature Properties

**094429 SPATIALLY RESOLVED OBSERVATION OF CURRENT FILAMENT DYNAMICS IN SEMICONDUCTORS.** Two-dimensional imaging of the nucleation and the dynamics of current filaments generated in homogenous p-doped germanium at 4.2 K during impurity impact ionization induced avalanche breakdown has been performed. The images were obtained by scanning the specimen surface with an electron beam and by recording the beam-induced current change in the voltage-biased samples. This new method is expected to identify in particular the filament configurations showing chaotic temporal resistance behavior. (Author abstract) 8 refs.

## Marketing

**094430 SPECIAL FEATURES OF GERMANIUM AND GALLIUM SUPPLY AND DEMAND.** Gallium and germanium both find their main uses in the electrical and electronics sector, more than three-quarters of total world consumption of germanium and more than 90% of that of gallium being attributable to electronic and optoelectronic applications. An attempt has been made to identify the main features that govern supply and demand and to explain how these characteristics distinguish them from the tonnage base metals that are traded on the world's metal exchanges. Technological factors associated with their production and usage rather than the availability and supply of their mineral ores are the principal determinants of market stability for both germanium and gallium. 13 refs.

Jacobson, D.M. (GEC Hirst Research Cent, Wembley, Engl). *Trans Inst Min Metall Sect C* v 97 Mar 1988, Proc of the Twelfth Annu Comm Mod Meet of the Inst of Min and Metall, London, Engl, Dec 3 1987 p 45-48.

**Optical Properties** See Also SEMICONDUCTING SILICON—Optical Properties.

**094431 FAR-INFRARED OPTICAL CONSTANTS, QUANTUM EFFICIENCY AND INTERNAL QUANTUM YIELD OF DETECTOR-QUALITY GALLIUM-DOPED GERMANIUM.** The temperature variations of the optical constants of detector quality gallium doped germanium have been determined between 4.7 and 295 K in the spectral region from 30 to  $130 \text{ cm}^{-1}$ . The 4.7 K absorption and refraction spectra were used to calculate the expected quantum efficiency of a Ge:Ga photoconductor having similar geometric and electrical characteristics to those used in earlier detector studies. A

comparison of this with measurements of the photoconductive response of such a detector allowed the spectral variation, of the internal quantum yield of photoexcited free carriers to be studied. (Author abstract) 13 refs.

## Oxidation

**094435 NATIVE OXIDES FORMED ON SINGLE-CRYSTAL GERMANIUM BY WET CHEMICAL REACTIONS.** The preparation of stable oxide films on single-crystal germanium surfaces by a room temperature 'wet' chemical oxidation technique is described. Characterization by IR-transmission, ellipsometry, x-ray photoelectron spectroscopy, Rutherford backscattering, and electron microscopy show that such films are dense, uniform, and free of defects. The oxides are a mixture of two germanium dioxide phases both of which have a cristobalite atomic configuration. Unlike hexagonal germania, these films are stable in both water and hydrofluoric acid. They can be totally converted to the hexagonal dioxide phase by heat-treatment in either oxygen or nitrogen ambient at  $600^\circ\text{C}$ . The growth kinetics, mechanisms and morphologies of the oxides formed by this method are presented. (Edited author abstract) 18 refs.

## Physical Properties

**094436 EXPERIMENTAL STUDY OF THREE GROUND STATE COMPONENTS OF THE HYDROGEN-OXYGEN DONOR IN GERMANIUM.** Experimental results are presented which show the existence of a ground state manifold consisting of at least three (IS) levels associated with the hydrogen-oxygen donor D(H,O) in ultra-pure germanium. Photothermal ionization spectra were recorded as a function of temperature. In addition to the transitions arising from the stress-insensitive ground state (GS), at  $T = 6K$ , a low intensity hydrogenic series of lines is observed with energies 2.51 meV smaller than from the GS, arising from a (IS) energy level lying 1.57 meV above the GS. Above 7K a further weak transition is observed at 2.97 meV less than the GS series, arising from an energy level 1.94 meV above the GS. A multicomponent (IS) manifold has been predicted by two theoretical models. Our experimental results allow the determination of the model parameters and are consistent with the predictions of the tunneling hydrogen model when an excited state splitting of 0.98 meV due to two nuclear configurations is included. (Edited author abstract) 16 refs.

## Radiation Effects

**094438 HIGH CONTRAST LASER WRITING IN IN SITU TEXTURED GERMANIUM FILMS VIA A NOVEL CHEMICAL OXIDE FORMATION.** A high contrast laser wiring technique based on laser induced efficient chemical oxidation in situ textured Ge films is demonstrated. Free running Nd-YAG laser pulses are used for irradiating the films. The irradiating effects have been characterized using optical microscopy, electron spectroscopy and microdensitometry. The mechanism for the observed contrast has been identified as due to formation of GeO<sub>2</sub> phase upon laser irradiation using X-ray initiated Auger spectroscopy (XAES) and X-ray photoelectron spectroscopy (XPS). The contrast in the present films is found to be nearly five times more than that known due to GeO phase formation in similar films. (Author abstract) 9 refs.

## Spectroscopic Analysis

**094439 PIEZO-SPECTROSCOPY OF THE C LINE OF GALLIUM IN GERMANIUM.** Experimental results are presented on the behavior of the C line of gallium

impurity in germanium under uniaxial compression along a  $\langle 100 \rangle$  direction. The C line stress spectrum is found to have ten components arising from the splitting of a complex final state consisting of the closely spaced combination:  $1\Gamma_7^- + 3\Gamma_8^- + 3\Gamma_8^+$ . The participation of the even parity state in the C transition has not been previously reported. Recent theoretical calculations are shown to give splitting values in agreement with these results. (Edited author abstract) 13 refs.

Vickers, R.E.M. (Univ of Wollongong, Wollongong, Aust); Fisher, P.; Freeth, C.A. *Solid State Commun* v 65 n 4 Jan 1988 p 271-274.

**094440 IR-SPECTROSCOPY OF IMPURITY COMPLEXES IN GERMANIUM.** A large number of impurity complexes which create shallow levels, have been discovered in pure and doped germanium single crystals. The structure and the composition of several of these complexes have been determined using far-infrared spectroscopy and information about crystal growth related residual impurities. In general, the complexes consist of a heavy substitutional impurity binding one or more light, interstitial impurities such as hydrogen or lithium. The coupling between the tunneling motion of the interstitial component and the electronic structure of the complexes can create complicated ground state manifolds which contain stress insensitive components. Spectroscopy further shows that multivalent centers, such as double or triple acceptors, become hydrogenic complexes upon binding one or two hydrogen atoms, respectively. Neutralization of shallow acceptors in silicon, which has recently attracted attention, appears to be the same phenomenon as the valency reduction of multiple acceptors in germanium. (Author abstract) 42 refs.

Haller, E.E. (Univ of California, Berkeley, CA, USA). *Physica B & C* v 146 n 1-2 Sep 1987, Shallow Impurity Cent in Semicond. Proc of the Second Int Conf on Shallow Impurity Cent/Fourth Trieste IUPAP-ICTP Semicond Symp, Trieste, Italy, Jul 28-Aug 1 1986 p 201-211.

## Spectrum Analysis

**094441 SATURATION OF INTERVALENCE-BAND TRANSITION IN P-TYPE GERMANIUM.** The nonlinear absorption saturation in P-Ge is investigated. Using the combined density of states for heavy and light hole valence bands and semiconductor energy band dispersion relation  $E(k)$ , from the imaginary part of the susceptibility, the absorption coefficient, which decreases with the increase of intensity in a manner similar to an inhomogeneously broadened two-level model, is obtained as  $\alpha(I, \omega) = \alpha_0(\omega) / [1 + I(\omega)/I_s(\omega)]^{1/2}$ . The quantitative relations between  $\alpha_0$ ,  $I_s$ , semiconductor parameters and the frequency of the incident light are deduced. The theoretical calculation is found to be in good agreement with the measured results. (Author abstract) 5 refs.

**094442 TIME-RESOLVED PICOSECOND INFRA-RED ABSORPTION INDUCED BY HIGH-DENSITY PHOTOGENERATED CARRIERS IN GE AND CDSE.** Picosecond time-resolved absorption at 2.2, 3.4, and 3.9  $\mu m$  produced by photogenerated carriers in intrinsic Ge and semi-insulating CdSe has been measured at room temperature. For Ge, the peak absorbance changes as the square of the probe wavelength. The absorption profile as a function of delay time relative to the excitation pulse rises with a resolution-limited risetime ( $< 10$  ps) and decays over the range from several hundred picoseconds to several nanoseconds. These observations can be accounted for by free-carrier absorption and Auger recombination. Intervalence transitions make a small contribution (approximately 17%) to the induced absorption only at 2.2  $\mu m$ . For CdSe, the absorption change with time exhibits a more complex profile, which is described and discussed. 25 refs.

**094443 PHOTOLUMINESCENCE AND INFRA-RED ABSORPTION STUDIES OF DOUBLE ACCEPTORS IN GERMANIUM.** Recent studies of double acceptors using near-, mid-, and far-infrared spectroscopy are reviewed, and new results are presented in each of these areas. Bound excitons and bound multiexciton complexes associated with these centers are investigated using photoluminescence and near-infrared absorption spectroscopy, and also measurements of the far-infrared absorption due to transitions between bound exciton states. Many bound exciton excited states are observed, and are well explained by a pseudo-donor model. The earlier predictions that the double acceptor ground states were split by hole-hole coupling, which were based upon near-infrared results and the temperature dependence of the mid-infrared neutral acceptor absorption, are verified by detailed uniaxial stress measurements of Ge:Be and Ge:Zn. (Author abstract) 47 refs.

Proc of the Second Int Conf on Shallow Impurity Cent/Fourth Trieste IUPAP-ICTP Semicond Symp, Trieste, Italy, Jul 28-Aug 1 1986 p 47-64.

**094444 ABSORPTION STRENGTHS IN THE FAR-IR SPECTRUM OF SHALLOW DONORS AND ACCEPTORS IN GERMANIUM.** The far-IR absorption spectrum of elemental shallow donors and acceptors in germanium has been studied as a function of the dopant concentration ( $10^{12}$ ,  $10^{14}$  at/cm<sup>3</sup>). The integrated absorption cross section and the oscillator strength have been determined for the main transitions from the ground state. The oscillator strength have been determined for the main transitions from the ground state. The oscillator strengths decrease gradually in the sequences Sb, P, As and B, Al, Ga, In, i.e. with the ground state becoming gradually deeper. Absorption spectra of compensated samples are also presented, illustrating the effect of band-gap illumination on the relative line strengths of the compensated as well as the compensating impurities. **094445 ZEEMAN SPECTROSCOPY OF IMPURITIES IN STRESS-INDUCED UNIAXIAL GERMANIUM.** A novel cryostat which permits the simultaneous application of a uniaxial compressive force and a uniform magnetic field to a crystalline solid has been used to study impurity spectra in semiconductors. The application of such a force along a  $\{100\}$  crystallographic direction, for example, converts germanium from cubic to tetragonal symmetry. The stress-modified line spectrum can then be studied using Zeeman spectroscopy. (Author abstract) 7 refs.

**Substrates See GERMANIUM COMPOUNDS—Thin Films.**

## Thin Films

**094446 SOME ELECTRICAL PROPERTIES OF MIXED AMORPHOUS THIN FILMS OF GERMANIUM AND SILICON MONOXIDE BEFORE ELECTROFORMING.** The co-evaporated SiO<sub>2</sub>-Ge system was studied. Thin-film MIM sandwich structures were depos-

ited by vacuum evaporation at a pressure of  $\approx 10^{-4}$  Pa and were measured at a pressure of  $10^{-3}$  Pa. The conductivity at low temperature and under d.c. fields has been found to be governed by a combination of an electronic hopping process and free-band conduction. At fields greater than  $2 \times 10^6$  V m $^{-1}$ , it is concluded that the conduction process is governed by the Poole-Frenkel effect. Comparison with earlier results on SiO $_2$ -GeO $_2$  films showed small differences in activation energy for conduction for samples of broadly similar overall composition. (Author abstract) 7 refs.

## Transport Properties

**094447 LOW-TEMPERATURE MAGNETORESISTANCE IN MEDIUM-ANGLE GRAIN BOUNDARIES IN GERMANIUM.** Magneto-transport properties of grain boundaries in germanium biocrystals are studied in the liquid helium temperature range. For samples with 7° and 9° tilt angle an exponential magnetic field dependence is observed, which is analyzed in terms of two-dimensional hopping conduction. The acceptor concentration N in the grain boundary can be deduced by comparing different magnetic field orientations. A surprising temperature dependence of N is obtained. In addition, the activation energy is determined as about 0.5 meV, typical for the hopping process, and decreases slightly with increasing magnetic field. (Author abstract) 8 refs.

## SEMICONDUCTING GERMANIUM COMPOUNDS

### Amorphous

**094448 AMORPHOUS Ge $_{1-y}$ Se $_y$  ALLOYS: ESR STUDY OF GAP STATES.** We have measured the ESR spectra of evaporated amorphous Ge $_{1-y}$ Se $_y$  alloy films. We find that with the addition of Se to a-Ge the spin density drops, the g-value decreases from  $2.0233 \pm 0.0007$  to  $2.012 \pm 0.002$  and there is an increase in asymmetry and linewidth. The results indicate that the Fermi level shifts into the conduction band tail with the addition of as little as 5 at.% Se and that the introduction of Se permits a significant reduction in the dangling bond density. (Author Abstract) 6 refs.

Pooke, D. (DSIR, Lower Hutt, NZ); Buckley, R.G.; Devine, S.; Trodahl, H.J. *Solid State Commun* v 62 n 5 May 1987 p 341-343.

**094449 CONTRAST-MATCHING SMALL-ANGLE NEUTRON-SCATTERING EXPERIMENTS ON OBLIQUELY EVAPORATED AMORPHOUS GeSe $_3$  FILMS.** Small-angle neutron-scattering contrast-matching experiments have been performed on obliquely deposited amorphous GeSe $_3$  films. The films are found to have two types of void: one anisotropic with a ratio of major to minor axes of about five; the other isotropic and a factor of ten smaller in volume. Although the scattering data are difficult to interpret, there is reason to believe that surface (roughness) scattering does not play the dominant role. (Author abstract) 8 refs.

Verrall, D. (Univ of Cambridge, Cambridge, Engl); Spence, C.A.; Elliott, S.R. *Philos Mag B* v 57 n 4 Apr 1988 p 445-453.

**094450 INVESTIGATION OF MEDIUM RANGE ORDER BY PHOTOEMISSION, REFLECTIVITY, LASER-INDUCED CRYSTALLIZATION RAMAN SPECTROSCOPY IN AMORPHOUS GeSe $_2$ .** It is difficult to determine the structure of amorphous materials, since the long range order is completely destroyed, where the conventional crystallographic diffraction method becomes less powerful. The authors report recent investigations for intermediate structures in amorphous GeSe $_2$  both by laser-induced crystallization Raman spec-

troscopy and photoemission and reflectivity spectra. 30 refs.

Murase, Kazuo (Osaka Univ, Toyonaka, Jpn); Inoue, Koichi. *Disord Semicond Publ* by Plenum Press, New York, NY, USA and London, Engl, 1987 p 297-306.

**094451 BONDING AND SHORT RANGE ORDER IN a-Ge $_x$ Te $_{1-x}$  ALLOYS.** Central to an understanding of the properties of amorphous semiconductors is a knowledge of their bonding coordination. An additional factor in alloy systems (A $_x$ B $_{1-x}$ ) is the degree to which randomly distributed bonds are replaced by heteropolar (A-B) bonds. Vibrational and electronic spectroscopy have proven powerful tools to elucidate these aspects of the structure. The authors present the results of far infrared absorption measurements, supported by Raman spectroscopy, over a wide range of a-Ge $_x$ Te $_{1-x}$  alloy composition. The data provide estimates of the density of GeTe $_4$  and Te-Te units as a function of composition. These densities are well predicted by a random network model containing the following features: 1. 4-2 fold coordination at all compositions. 2. A weak but systematic chemical order, with the density of heteropolar bonds lying approximately one third of the way from the CRN to the COCRN densities. 18 refs.

Fee, M.G. (Victoria Univ of Wellington, Wellington, NZ); Trodahl, H.J. *Disord Semicond Publ* by Plenum Press, New York, NY, USA and London, Engl, 1987 p 307-315.

**094452 PHOTOACOUSTIC SPECTRA OF AMORPHOUS SEMICONDUCTORS Ge $_{20}$ S $_{80-x}$ Bi $_x$ .** A study of the amorphous semiconductors Ge $_{20}$ S $_{80-x}$ Bi $_x$  by photoacoustic spectroscopy in the spectroscopy in the spectral range 200 nm to 2600 nm has been undertaken for the first time. The three regions of the optical absorption edge of the semiconductors (i) Urbach's tail, (ii) the subband tail due to localized tail states, and (iii) the interband transition region above the fundamental absorption edge, have been observed. Bismuth impurity induced structural modification in the parent Ge-S glass, which is responsible for p-n transition in these semiconductors, is reflected in the optical absorption spectrum. (Author abstract) 17 Refs.

Bhatia, K.L. (Maharshi Dayanand Univ, Rohtak, India); Bhatnagar, V.K. *J Non Cryst Solids* v 104 n 1 Aug 1988 p 17-21.

**094453 STRUCTURAL MODELS OF AMORPHOUS GeS.** We have constructed two hand-built CRN structural models of a-GeS. We have assumed 4:2 coordination for the Ge and S atoms respectively, and allowed only Ge-S and Ge-Ge bonds. The models contain 430 and 350 atoms. They differ both by the statistics of the tetrahedra Ge(Ge $_{4-p}$ S $_p$ ) and by their medium-range order. The first model corresponds to a three-dimensional network with random statistics for the tetrahedra, the second one represents a layered structure built mainly of Ge(Ge $_2$ S $_2$ ) units. The models were relaxed with respect to the Keating potential. Comparison of the calculated and observed structural characteristics, density and radial distribution function (RDF), showed that the structure of a-GeS may be represented by the three-dimensional CRN, but not by the layered model. (Edited author abstract) 37 Refs.

## Chemical Vapor Deposition

**094454 PREPARATION OF GERMANIUM NITRIDE FILMS BY LOW PRESSURE CHEMICAL VAPOR DEPOSITION.** Germanium nitride (Ge $_3$ N $_4$ ) was deposited onto polished germanium wafers by low pressure chemical vapor deposition (LPCVD). Depositions were performed in a hot-wall quartz tube system at temperatures from 450° to 600°C, using GeCl $_4$  and NH $_3$  reactants. Details of the deposition procedure and apparatus are reported. Deposition rates of 5-50 Å per min were obtained, yielding films having refractive indexes of

$2.05 \pm 0.05$ , as measured by ellipsometry. The dependence of deposition rate on temperature and gas flow parameters is reported. Infrared transmission data, as well as etch rate data, are also presented. (Edited author abstract) 21 refs.

## Crystallization

**094455 CRYSTALLIZATION KINETICS OF GLASSY GeSe $_2$ .** The crystallization kinetics of glassy GeSe $_2$  was investigated by non-isothermal heat flux differential scanning calorimetry (DSC) on both bulk and powder samples. It was shown that high-temperature modification of germanium disulphide crystallizes from an undercooled melt of composition GeSe $_2$ . The crystallization kinetics can be described by the Sestak-Berggren (SB) kinetic model, using the Arrhenius dependence of the rate constant. It was found that the Johnson-Mehl-Avrami (JMA) kinetic model is less suitable for the description of the studied crystallization process. A BASIC program has been written for both SB and JMA models to evaluate kinetic data from experimental DSC curves recorded with the Perkin-Elmer Thermal Analysis Data Station system. (Author abstract) 21 refs.

## Microscopic Examination

**094456 STRUCTURE OF IODINE-DOPED POLY-GeO-PHTHALOCYANINE EPITAXIAL FILM AND ITS LATTICE DEFECTS STUDIED BY DIRECT ATOM IMAGING.** The process of iodine doping into poly-GeO-phthalocyanine (GeOPc) thin films has been studied by high-resolution electron microscopy (2.0 Å resolution; 200 kv). The doped GeOPc is isomorphic with NiPc, CoPc, FePc, H $_2$ Pc-halogen complexes. The doping is initiated from the stacking fault plane and the expansion of the lattice due to the penetration of iodine is 2.6 Å at the faulted planes while it is only 0.2 Å in the regular part of the crystal. The molecular arrangement and iodine position at the defect are directly determined visually. (Author abstract) 11 refs.

Kobayashi, Takashi (Kyoto Univ, Uji, Jpn); Uyeda, Natsuo. *Philos Mag B* v 57 n 4 Apr 1988 p 493-504.

## Microstructure

**094457 PLANAR DEFECTS IN GeSe AND GeS CRYSTALS.** Planar defects in layered GeSe and GeS crystals grown by vapor transport were studied by transmission electron microscopy. The principal defects are (110) twins which appear as narrow parallel bands and (001) low-angle grain boundaries containing networks of boundary dislocations. In order to propose an atomistic model, the structure of the materials is described in terms of hexagonal rings and trigonal pyramids projected along the c-axis. These units are used for the construction of a model of the twin structure which is free of dangling bonds. The relationship of the defects with transport properties is discussed. (Author abstract) 12 Refs.

**Optical Properties See Also SEMICONDUCTING TIN COMPOUNDS—Optical Properties.**

## 094458 TEMPERATURE DEPENDENCE OF

**TWO-DIMENSIONAL OPTICAL ENERGY GAP FOR GERMANIUM SELENIDE SINGLE CRYSTALS.** The interband absorption coefficient of GeSe single crystals near the fundamental absorption edge is analyzed on the basis of a two-dimensional model and is found to correspond to an indirect forbidden transition. The optical energy gap at room temperature is found to be  $(1.066 \pm 0.011)$  and  $(1.078 \pm 0.010)$  eV for the a- and c-crystallographic axes, which lie in the plane of cleavage. The temperature dependence of the two-dimensional optical energy gap is studied from room temperature to near liquid nitrogen temperature. This dependence is found to be linear in the range from 96 to 250 K with a negative temperature coefficient  $dE_g/dT$  equal to  $-0.48$  and  $-0.46$  meV per K for the a- and c-axes, respectively. The results are compared with those obtained on basis of three dimensional model and agreement is found to be within the limits of experimental error. (Author abstract) 13 refs.

## Order-Disorder

**094459 SHORT-RANGE ORDER IN SOME ALLOYS OF THE Ge-As-Te SEMICONDUCTING GLASSY SYSTEM BY X-RAY DIFFRACTION.** A study of short-range order in amorphous semiconducting alloys of the Ge-As-Te system has been carried out by x-ray diffraction. The different hypothesis on germanium coordination have been taken into account, following the different criteria cited in the literature for binary Ge-Te alloys. The result of this study shows the possibility of structural units based on tetra- or tricoordinated germanium atoms, which bonded together give way to short-range order in these alloys. It has also been found that, for these alloys, germanium dicoordination is not compatible with the data obtained experimentally. (Author abstract) 22 refs.

Ligero, R.A. (Univ de Cadiz, Cadiz, Spain); Vazquez, J.; Villares, P.; Jimenez-Garay, R. *J Mater Sci* v 22 n 12 Dec 1987 p 4357-4361.

## Physical Properties

**094460 STRUCTURE AND TRANSPORT PROPERTIES OF AMORPHOUS  $Ge_{1-x}C_x:H$  THIN FILMS OBTAINED BY ACTIVATED REACTIVE EVAPORATION.** Hydrogenated amorphous germanium-carbon ( $a-Ge_{1-x}C_x:H$ ) thin films have been prepared by an activated reactive evaporation technique. Germanium was evaporated from a resistively heated tungsten basket through an acetylene plasma. The films thus obtained were characterized for the compositional, structural, electrical and optical properties. The effects of substrate temperature, role of hydrogen and variation of optical energy gap with carbon content were also investigated. Typically, films deposited at 200°C showed a sharp absorption edge corresponding to an optical gap of about 1.3 eV and thermally activated electrical conduction over a wide range of temperatures. (Author abstract) 11 refs.

Kumar, Sunil (Indian Inst of Technology, New Delhi, India); Kashyap, Subhash C.; Chopra, K.L. *J Non Cryst Solids* v 101 n 2-3 May 1988 p 287-290.

## Radiation Effects See FILMS—Doping.

## Spectroscopic Analysis

**094461 INFRARED LATTICE VIBRATIONS IN  $Cu_2GeSe_3$ .** Infrared reflectivity spectra of  $Cu_2GeSe_3$  are measured at room temperature in the wave-number range from 180 to 4000  $cm^{-1}$ . From an analysis of the spectra the parameters of four vibrational modes are determined. The experimental results are compared with predictions from group theory. From a comparison of the results of  $Cu_2GeSe_3$  with the vibrational characteristics of other chalcogenides it follows that the force constants of cation-chalcogen bonds increase with increasing valence of the cation. (Author abstract) 14 refs.

Riede, V. (Karl-Marx-Univ, Leipzig, East Ger); Sharif, N.; Neumann, H.; Sobotta, H.; Omar, M.S.; Pamplin, B.R. *Cryst Res Technol* v 22 n 8 Aug 1987 p 1089-1093.

**094462 ON THE MASS TRANSPORT PROPERTIES OF THE GeSe-Ge<sub>4</sub> SYSTEM UNDER NORMAL AND REDUCED GRAVITY CONDITIONS.** With respect to the mass spectrometric observations by Buchan and Rosenberger, our earlier mass transport rate studies of the GeSe-Ge<sub>4</sub> system are re-evaluated considering the presence of GeSe(s) and GeSe<sub>2</sub>(s) phases in the source material. The previously derived dominance of the sublimation of GeSe at lower ( $<0.05$  atm) and of chemical vapor transport at higher ( $>0.1$  atm) pressures of Ge<sub>4</sub> has also been concluded from the current analysis of the transport system. The nature of the dominant CVT process(es) is apparently different from that proposed earlier, and is not known at this time. The experimentally observed flux anomalies are independent of a given model. The limitations of the previous and current models for the GeSe-Ge<sub>4</sub> system are discussed. (Author abstract) 26 refs.

**094463 ELECTRON SPIN RESONANCE OF  $Mn^{2+}$  IN Bi DOPED n-TYPE AMORPHOUS GERMANIUM CHALCOGENIDE SEMICONDUCTORS.** Electron spin resonance of Bi doped  $Ge_{20}S_{79.5-x}Bi_xMn_{0.5}$  glassy semiconductors has been observed using transition metal Mn as a microprobe for the first time. At lower Bi concentrations ( $x=4$ ) one resonance line at  $g \approx 2$  is observed whereas in  $x=11$  &  $x=15$  composition another line at  $g \approx 4$  appears. It is suggested that Bi atoms in Sulfur rich germanium sulfide glass occupy two different types of sites in the material at low (4 at%) and high 11, 15 at%) Bi concentrations respectively. (Author abstract) 8 refs.

Bhatia, K.L. (Maharshi Dayanand Univ, Rohtak, India); Bhatnagar, V.K.; Gosain, D.P. *Key Eng Mater* v 13 pt 3 1987, Int Conf on Met and Semicond Glasses (MSG-86), Hyderabad, India, Dec 16-20 1986 p 623-626.

## Surfaces

**094464 NATURAL SURFACE FILMS ON GeS.** GeS belong to a group of layer-like orthorhombic chalcogenides which have attracted considerable interest in recent years. The present note reports results on the growth of a natural surface film on the cleaved surface of a p-type single crystal. To get information about the properties of cleaved surfaces of this material with respect to possible contamination, the author studied the changes of the ellipsometric angles with time. 3 refs.

**094467 NON-ISOTHERMAL CRYSTALLIZATION OF  $Bi_2S_3$  FROM GLASSY  $(GeS_2)_{0.5}(Bi_2S_3)_{0.5}$ .** The non-isothermal kinetics of crystallization of  $Bi_2S_3$  from glassy  $(GeS_2)_{0.5}(Bi_2S_3)_{0.5}$  is examined using differential scanning calorimetry. Several kinetic models related to different mechanisms are tested. The best fit to the experimental data is obtained assuming that the transformation fulfills the equation  $f(\alpha) = \alpha^m(1 - \alpha)^n$ , where  $\alpha$  is the fraction of crystallized material. (Author abstract) 7 refs.

Tichy, L. (Univ of Chemical Technology, Pardubice, Czech); Nagels, P. *Phys Status Solidi A* v 107 n 2 Jun 1988 p 769-774.

**094468 PROPERTIES OF SEMICONDUCTIVE GLASSES IN THE  $V_2O_5$ -CuO SYSTEM.** In this work a range of rapidly quenched glassy films in the  $V_2O_5$ -CuO system were prepared and their crystallization processes, IR absorption spectra and electrical conductivities were investigated. The electrical conductivity of the quenched glassy films is discussed from the standpoints of the reduction of  $V^{5+}$  ion and the glass structure. With increase of CuO content, the amount of reduction increases, whereas the electron hopping paths through V-O-V bonds decreased. Overall, the electrical conductivity of the quenched films increased with the increase of CuO content, mainly due to the increase of  $V^{4+}$  ion. 10 refs.

## Defects

**094469 POSITRON ANNIHILATION STUDY OF DEFECTS AND MICROHETEROGENEITY OF CHALCOGENIDE GLASSY SEMICONDUCTORS.** Chalcogenide glassy semiconductors (CGS) - compounds of chalcogens (S, Se, Te) with the elements Ge, As, Si - are closely studied using various techniques because of the wide technical applications of these materials. A substantially new result of this positron annihilation (PA) study in comparison with previous investigations consists in identification of positron annihilation mechanisms in CGS and in demonstration of a very high sensitivity of PA-technique to CGS - defects responsible for their electric and optical properties. The typical positron annihilation lifetimes are found. A satisfactory explanation of both the lifetime and annihilation radiation angular correlation data using the so-called 'optical' model provides a test of the positron annihilation mechanism in CGS. (Edited author abstract)

Shantarovich, V.P. (Acad of Sciences of the USSR, Moscow, USSR); Kobrin, B.V. *Key Eng Mater* v 13 pt

3 1987, Int Conf on Met and Semicond Glasses (MSG-86), Hyderabad, India, Dec 16-20 1986 p 639-640.

## Dielectric Properties

**094470 DIELECTRIC PROPERTIES OF SEMI-CONDUCTING GLASSES.** The dielectric behavior or the response of a material under an applied ac signal has been considered in different ways by the workers from dielectric and semiconductor schools. This has resulted into different ways of the presentation of dielectric data, the correlation and advantages of these different representations are briefly discussed. The experimental data over a wide temperature and frequency region in transition metal oxide (TMO) glasses is critically examined to demonstrate two distinct regions of dielectric response. In the high frequency region both the dielectric constant and dielectric loss show little dependence on frequency. In the low frequency region the dielectric constant and dielectric loss show a large dispersion. A plausible qualitative model for explaining the dielectric behavior of semiconducting glasses over a wide frequency range is presented. (Edited author abstract)

Mansingh, Abhai (Univ of Delhi, Delhi, India). *Key Eng Mater* v 13 pt 3 1987, Int Conf on Met and Semicond Glasses (MSG-86), Hyderabad, India, Dec 16-20 1986 p 895-896.

## Differential Thermal Analysis

**094471 NATURE OF DEFECTS IN AMORPHOUS Bi-Se ALLOYS.** Differential thermal analysis results concerning  $\text{Bi}_x\text{Se}_{1-x}$  alloys ( $0 < x < 0.27$ ) show that Bi atoms may be either three- or four-fold coordinated. Further measurements of dark conductivity show a sharp decrease in both resistivity and activation energy of conductivity between 1 and 2 at% Bi. Comparison with other Bi-based alloys and chalcogenide alloys without Bi leads to the conclusion that Bi plays a particular role when allied with chalcogenide materials. Consideration concerning the metallic character and electronegativity of Bi enable us to confirm that in Bi-based chalcogenide alloys the Bi defects are four-fold coordinated and positively charged. (Edited author abstract). 36 Refs.

## Doping See Also GLASS, METALLIC—Ionic Conduction.

**094472 ELECTRICAL CONDUCTIVITY OF SEMI-CONDUCTING BARIUM ALUMINOPHOSPHATE GLASSES CONTAINING SINGLE AND DOUBLE REDOX PAIRS.** In systems with TM (Transition Metal)-oxides incorporated in pairs the probability of hopping processes significantly depends on the oxidation potential or on the electrochemical series of the redox pairs, respectively, because the electronic charge carrier concentration depends on the mutual shift of the redox equilibria. Those hopping processes which are not conform to this shift have a very low probability. Therefore, increasing or decreasing conductivity in those mixed redox pairs containing systems depends primarily on the electrochemical series and on the initial redox situation of that redox pair and its redox shift, which dominates the electrical conductivity. (Edited author abstract) 39 refs.

**094473 EFFECT OF IRON IMPURITY ON ESR AND ELECTRICAL PROPERTIES OF BIS-MUTH-VANADATE GLASSES.** It is well known that the semiconducting properties of the transition metal ion glasses are due to the presence of transition elements in various valence states. The present work aims to study the interaction between vanadium and iron ions in  $\text{V}_2\text{O}_5$ - $\text{Bi}_2\text{O}_3$  glasses doped with  $\text{Fe}_2\text{O}_3$ . The electrical conductivity of the bismuth-vanadate glasses is greatly affected by the addition of  $\text{FeO}_3$ . For the glasses containing  $\text{Fe}_2\text{O}_3$

, content up to 10 mol %, the electrical conduction takes place due to the electron hopping between various TMI hopping centres. The conduction due to the hopping mechanism goes on decreasing as the  $\text{Fe}_2\text{O}_3$  content is increased to more than 10 mol %. This is because more of the iron ions are situated in some kind of clusters and interaction pairs due to the Fe-O-Fe and Fe-O-V bonds formations. 11 refs.

**094474 EFFECT OF Cu DOPING ON THE DC CONDUCTIVITY AND THERMOELECTRIC POWER OF  $\text{As}_2\text{Se}_3$ -BASED GLASSES.** The dc conductivity and the thermoelectric power of  $\text{As}_2\text{Se}_3\text{Cu}_x$  and  $\text{As}_2\text{Se}_{1.5}\text{Te}_{1.5}\text{Cu}_x$  glasses ( $x = 1.0$  and  $1.67$ ) were measured as a function of temperature. Band-like conduction is observed with holes as dominant charge carriers. The addition of Cu leads a decrease in the activation energies for conduction which is correlated with the change in the density of states of the valence band. (Author abstract). 15 Refs.

Abe, H. (Hokkaido Univ, Sapporo, Jpn); Nakamura, Y. *Phys Status Solidi A* v 107 n 1 May 1988 p 315-319.

**094475 EFFECT OF COPPER AND LEAD ON THE PROPERTIES OF As-Ge-X(X/S, Se, Te) GLASSES -POSITRON ANNIHILATION STUDIES.** The positron annihilation and electron microscopy techniques as well as measurements of electroconductivity and density were used for studies of As-Ge-X (S=S, Se, Te) glassy semiconductor doped with copper and lead. The influence of doping appeared to be dependent on the dopant amount and on the type of chalcogen. New units of structure-three-component compounds of metal with elements of glass, were identified in some cases. The doping effects were different in the case of disordered distribution of these units in the glass matrix and for their associations. The positron annihilation data were used for interpretation of the results of conductivity measurements. (Author abstract) 1 ref.

## Electric Conductivity

**094476 ELECTRICAL CONDUCTION IN CADMIUM GERMANATE GLASSES.** Preliminary conductivity data are reported for a series of novel cadmium germanate glass compositions. All systems studies are electronic conductors with small activation energies. The highest in CdO-content sample,  $0.56\text{CdO} \cdot 0.44\text{GeO}_2$ , is found to exhibit  $\sigma_{300\text{K}} \approx 100$  mho/cm. Correlations are attempted between the transport properties and the structural characteristics of these glasses. (Author abstract) 11 refs.

Chrysikos, G.D. (Nat'l Hellenic Research Foundation, Athens, Greece); Kamitsos, E.I.; Swiatek, J. *Solid State Commun* v 63 n 7 Aug 1987 p 615-618.

**094477 ON ELECTRONIC CONDUCTION IN THE PRE-SWITCHING REGION OF GLASSY SEMI-CONDUCTING ALLOYS  $\text{As}_{40}\text{Se}_{30}\text{Te}_{30}$  AND  $\text{As}_{20}\text{Se}_{50}\text{Te}_{30}$ .** The off-state direct current I-V characteristics for glassy alloys  $\text{As}_{40}\text{Se}_{30}\text{Te}_{30}$  and  $\text{As}_{20}\text{Se}_{50}\text{Te}_{30}$  at different temperatures were studied. For this study of electrical conduction properties, two kinds of electrode configurations were used: a double-point contact on one surface and a sandwich device. It was found that current flow can be space-charge limited, producing non-ohmic behavior, which in turn reflects on the electrical switching effect that the materials exhibit. The influence of the selenium content on the electrical properties was also studied. The experimental results obtained were compared with those in the literature, and the differences justified by the method of material preparation. Lastly, the depen-

dence of ohmic resistance on temperature was analyzed, and the characteristic behavior of intrinsic semiconduction observed. (Author abstract) 20 refs.

Marquez, E. (Univ de Cadiz, Cadiz, Spain); Villares, P.; Jimenez-Garay, R. *Mater Sci Eng* v 100 Apr 1988 p 229-234.

**094478 ANOMALOUS CONDUCTIVITY AND OTHER PROPERTIES OF  $\text{V}_2\text{O}_5$ - $\text{P}_2\text{O}_5$  GLASSES WITH  $\text{Bi}_2\text{O}_3$  OR  $\text{Sb}_2\text{O}_3$ .** To characterize  $\text{V}_2\text{O}_5$ - $\text{P}_2\text{O}_5$  glasses with  $\text{Bi}_2\text{O}_3$  or  $\text{Sb}_2\text{O}_3$ , the dc and ac conductivities and dielectric constants were measured, and SEM, x-ray diffraction, and DTA studies were made. The electric properties were measured in the temperature range 80-420 K and in the frequency range 0.1-100 kHz. The dc conductivity of the  $50\text{V}_2\text{O}_5(50-x)\text{P}_2\text{O}_5\text{-xBi}_2\text{O}_3$  ( $x=5-40$  mol%) glasses is found to be always higher than that of the pure base glass  $50\text{V}_2\text{O}_5\text{-P}_2\text{O}_5$ , while the dc conductivity of the  $50\text{V}_2\text{O}_5(50-x)\text{P}_2\text{O}_5\text{-xSb}_2\text{O}_3$  glasses is always lower than that of the base glass. Above 200 K, the activation energy of the  $\text{V}_2\text{O}_5$ - $\text{P}_2\text{O}_5$ - $\text{Bi}_2\text{O}_3$  glass depends on the concentration of  $\text{Bi}_2\text{O}_3$ , while that of the  $\text{V}_2\text{O}_5$ - $\text{P}_2\text{O}_5$ - $\text{Sb}_2\text{O}_3$  glasses is almost independent of the  $\text{Sb}_2\text{O}_3$  concentration. However, both of these glasses show an interesting conductivity minimum for about 25-30 mol% of  $\text{Bi}_2\text{O}_3$  or  $\text{Sb}_2\text{O}_3$ . This behavior was not found earlier in any such transition metal oxide glasses. The anomalous behavior is also observed in the concentration ( $\text{Bi}_2\text{O}_3$  or  $\text{Sb}_2\text{O}_3$ ) dependence of the density, glass transition temperature  $T_g$ , ac conductivity, and dielectric constant data. (Edited author abstract). 29 Refs.

Ghosh, Aswini (Indian Assoc for the Cultivation of Science, Calcutta, India); Chaudhuri, B.K. *J Non Cryst Solids* v 103 n 1 6(II) 1988 p 83-92.

**094479 ELECTRICAL CONDUCTIVITY OF VANADIUM PHOSPHATE GLASSES CONTAINING ZNO OR  $\text{GeO}_2$ .** The conduction mechanism of vanadium phosphate glasses containing ZnO or  $\text{GeO}_2$  is discussed in comparison with that of  $\text{PbO-V}_2\text{O}_5\text{-P}_2\text{O}_5$  glasses. Especially, the effect of  $\text{V}_2\text{O}_5$  concentration on the conductivity and the glass structure is discussed. 17 Refs.

Hirashima, Hiroshi (Keio Univ, Yokohama, Jpn); Kurokawa, Haruki; Mizobuchi, Katsuo; Yoshida, Teturo. *Glastech Ber* v 61 n 6 Jun 1988 p 151-156.

**094480 CONDUCTIVITY MINIMUM OF THE  $\text{V}_2\text{O}_5$ - $\text{P}_2\text{O}_5$  GLASSES CONTAINING  $\text{Bi}_2\text{O}_3$  OR  $\text{Sb}_2\text{O}_3$ .** A minimum in the dc and ac conductivities, dielectric constant, glass transition temperatures and density observed in the glasses  $50\text{V}_2\text{O}_5(50-x)\text{P}_2\text{O}_5\text{-XMO}$  with  $\text{MO}=\text{Bi}_2\text{O}_3$  or  $\text{Sb}_2\text{O}_3$  at  $x \approx 25-30$  mol% of MO is found to be due to the lowest value of the ratio  $V^{5+}/V^{4+}$  appearing at the same concentration of MO. The conductivity data for a particular concentration could, however, be well fitted with the Mott's polaron theory. The glass forming oxides also affect the activation energy for hopping conduction. (Author abstract) 9 refs.

**094482 IR SPECTROSCOPIC AND D.C. RESISTIVITY STUDIES OF BARIUM-VANADATE GLASSES.** Vanadium ions in  $\text{V}_2\text{O}_5$  are known to exist in two different valence states;  $\text{V}^{4+}$  and  $\text{V}^{5+}$ . The electrical conduction is believed to occur by electron hopping between  $\text{V}^{4+}$  and  $\text{V}^{5+}$  ions. Owing to the semiconducting nature, the glasses containing  $\text{V}_2\text{O}_5$  in amorphous state. In the present work systematic studies of barium-vanadate glasses containing iron are reported. A series of amorphous samples  $3\text{BaO} \cdot (0.9-Z) \text{V}_2\text{O}_5 \cdot 0.1\text{Fe}_2\text{O}_3$  with Z varying from 0.15 to 0.45 are prepared by pouring the melt on to a cold copper surface. The variations of resistivity and activation energy with composition are explained on the basis of the structure of these glasses. (Edited author abstract)

## Electric Properties

**094483 MODEL FOR THE CHEMICAL MODIFICATION OF ELECTRICAL PROPERTIES OF CHALCOGENIDE GLASSES BY BISMUTH.** A mechanism is proposed to account for the ability of Bi to change the electrical properties of certain chalcogenide glasses. EXAFS experiments have shown that there is a significant change in the local structural environment of the Bi at compositions close to the critical concentration of Bi (10at.%) at which the p-n transition takes place. These structural changes are interpreted in terms of a model in which the type of bonding at the Bi sites changes from covalent to partially ionic. The presence of charged impurity centres upsets the equilibrium between native charged defects in the glass, and a p-n 'doping' transition subsequently occurs at a critical impurity concentration. (Author abstract) 47 refs.

Elliott, S.R. (Univ of Cambridge, Cambridge, Engl); Steel, A.T. *J Phys C Solid State Phys* v 20 n 27 Sep 30 1987 p 4335-4357.

**094484 STRUCTURAL AND ELECTRICAL PROPERTIES OF THE GLASSY SEMICONDUCTOR SYSTEM Cu-As-Te.** A method has been developed for measuring electrical conductivity in bulk samples of glassy semiconductors based on the procedure described by L.B. Valdes which is used to determine the conductivity of  $\text{Cu}_{0.05}\text{As}_{0.50}\text{Te}_{0.45}$  and  $\text{Cu}_{0.15}\text{As}_{0.40}\text{Te}_{0.45}$ . The experimental results are justified by structural models corresponding to the compositions. The estimates of the number of bonds of each of the possible types as well as their ionization energies are used for this purpose. This analysis is preceded by a description of an electrical conduction model. Results on the properties of electrical switching are given. (Edited author abstract) 23 refs.

Marquez, E. (Univ de Cadiz, Puerto Real, Spain); Vazquez, J.; de la Rosa-Fox, N.; Villares, P.; Jimenez-Garay, R. *J Mater Sci* v 23 n 4 Apr 1988 p 1399-1404.

## Electronic Properties

**094485 ELECTRONIC PROCESSES IN OXIDE GLASSY SEMICONDUCTORS AND THIN-FILM STRUCTURES BASED ON THEM.** The physical nature of electronic processes in oxide glassy semiconductors (OGS) based on  $\text{V}_2\text{O}_5$  is discussed on the basis of the theory of the small-radius polaron (SRP). The most important parameters of the process of charge transfer by polarons are determined from an analysis of the temperature dependence of the static conductivity by mathematical

modeling employing general theoretical expressions. A model of coupled SRP, presuming that they are localized by the Coulomb field of the charged defect centers, is proposed for describing the results on the effect of a strong electric field and dielectric relaxation. On the basis of the model, expressions describing the dependence of the current density and dielectric constant on the dc electric field strength and also a relation determining the dielectric relaxation time for the given model are obtained. The results of studies of the electric properties of OGS modified by additions of a second transition-metal oxide are also discussed. (Author abstract) 61 refs.

Gaman, V.I. (Tomsk State Univ, USSR); Kosintsev, V.I.; Kalygina, V.M. *Sov Phys J* v 30 n 6 Jun 1987 p 461-474.

**094486 EXPONENTIAL BAND TAILS AS A CONSEQUENCE OF THE GLASS TRANSITION.** A recently proposed theory for the glass transition is briefly reviewed. The theory predicts two different kinds of glass transitions, slow and fast. It is argued that glassy semiconductors prepared from a fast glass transition have exponential band tails of localized states. (Author abstract) 21 refs.

Dyre, J.C. (Roskilde Univ Cent, Roskilde, Den). *Key Eng Mater* v 13 pt 2 1987, Int Conf on Met and Semicond Glasses (MSG-86), Hyderabad, India, Dec 16-20 1986 p 501-504.

**094487 POSITRONIUM PICK-OFF LIFE TIMES IN  $\text{V}_2\text{O}_5$ - $\text{TeO}_2$  CuO SEMICONDUCTING GLASSES.** The ternary glass system  $(\text{V}_2\text{O}_5)_{0.55-x}(\text{CuO})_x(\text{TeO}_2)_{0.45}$  exhibits a complex behavior due to the formation of  $\text{V}^{4+}$ ,  $\text{V}^{5+}$ ,  $\text{Cu}^+$  and  $\text{Cu}^{2+}$  ions. As  $\text{V}_2\text{O}_5$  is partially replaced by CuO, electron transfer can take place between  $\text{V}^{4+}$  ( $3d^1$ ) and  $\text{Cu}^{2+}$  ( $3d^9$ ) leading to a decrease in  $\text{V}^{4+}$  ion concentration. This is confirmed by ESR studies when at 5 mol % CuO the  $\text{V}^{4+}$  resonance is completely suppressed. Thus there is a change in the paramagnetic ion concentration with composition. Since one of the important quenching modes of positronium is pick-off through paramagnetic ions we expect the positron lifetime to reflect this variation. (Edited author abstract) 6 refs.

Veena, K. (Univ of Hyderabad, Hyderabad, India); Sunandana, C.S.; Bansal, C. *Key Eng Mater* v 13 pt 3 1987, Int Conf on Met and Semicond Glasses (MSG-86), Hyderabad, India, Dec 16-20 1986 p 633-636.

**094488 STUDY OF SECONDARY ELECTRON EMISSION CHARACTERISTICS IN BISMUTH CONTAINING SEMICONDUCTING GLASSES.** A study of electron emissive characteristic is presented for bismuth containing vanadium pentoxide and silicate glasses. Measurements of yield in secondary electron emission (SEE) were performed incorporating a retarding field analyzer and the other related parameters such as work function and ionization potential were measured using a low energy electron gun. All measurements were made in ultra high vacuum conditions at pressure less than  $10^{-9}$  Torr. X-ray diffraction (XRD) was used to identify the metal contents in these glasses. On the basis of the experimental results, applications of these glasses in electron multipliers is proposed. (Author abstract)

## Heat Transfer

**094489 THERMAL INSTABILITY IN THE LASER-DRIVEN MELTING AND RECRYSTALLIZATION OF THIN SILICON FILMS ON GLASS SUBSTRATES.** This paper develops a conductive heat transfer stability theory for the laser-driven melting and recrystallization of thin silicon films deposited on conductive (glass) substrates. The important parameters are: laser power, laser intensity distribution, and beam scanning speed. Basic state temperature distributions are obtained for straight phase boundaries. These calculated temperature distributions show the origin of instability. A linear

perturbation analysis is used to obtain the leading order corrections to the basic-state temperature fields. The perturbation time rate of growth, as a function of the disturbance wavelength, is then predicted. (Author abstract) 18 refs.

Grigoropoulos, C.P. (Columbia Univ, New York, NY, USA); Buckholz, R.H.; Domoto, G.A. *J Heat Transfer Trans ASME* v 109 n 4 Nov 1987 p 841-847.

## Heat Treatment

**094490 QUANTUM SIZE EFFECTS IN HEAT TREATED, Cd(S,Se) DOPED GLASSES.** Fine semiconductor particles of different sizes can be grown in a doped glass by appropriate heat treatment. Changes in the corresponding optical absorption spectra result from quantum confinement effects. These changes are related to particle size and allow growth and coarsening kinetics to be determined. (Author abstract) 17 refs.

## High Pressure Effects

**094491 HIGH-PRESSURE STUDIES ON Ge-Te GLASSES EVIDENCE FOR A CRITICAL COMPOSITION IN IV-VI CHALCOGENIDE GLASSY SYSTEMS.** The electrical resistivity of bulk  $\text{Ge}_x\text{Te}_{100-x}$  glasses has been measured as a function of temperature and pressure. Under high pressure, all the glasses were found to undergo sharp discontinuous transitions from glassy semiconductors to crystalline metal. Several of the observed properties such as the transition pressure, conductivity activation energy and pre-exponential factor, exhibit anomalous trends at a composition  $x = 20$ . These results suggest that the  $x = 20$  composition in the Ge-Te system should possess salient structural features. A model based on the unusual stability of certain structural units is proposed for explaining the anomaly at 20 at.% Ge concentration. (Edited author abstract) 41 refs.

## Impurities

**094492 OPTICAL MONITORING OF PHOTODISSOLUTION KINETICS IN AMORPHOUS AS-S FILMS.** The kinetics of the photodissolution of silver into amorphous As-S films of various compositions in the range  $\text{As}_{40}\text{S}_{60}$  to  $\text{As}_{20}\text{S}_{80}$  has been investigated by monitoring the changes that occur in their reflectivity during the photodissolution process. As the S content was increased above 60 at.% the rate of photodissolution increased to a maximum at around  $\text{As}_{33}\text{S}_{67}$  and then decreased, the maximum rate being approximately double that for  $\text{As}_{20}\text{S}_{80}$ . This is attributed to the fact that only compositions within a few at.% of  $\text{As}_{33}\text{S}_{67}$  yield a homogeneous material when photodoped. The effect of using silver-copper alloys as the metal source instead of pure silver was found to increase the photodissolution rate by up to 12%. The photodissolution rate and the form of the time dependence of the process were dependent on the thickness of the silver layer used as the ion source. Thin silver films yield a slower rate and a diffusion-limited process whereas thick films yield a faster rate and a reaction-limited process. (Edited author abstract) 24 refs.

## Magnetic Properties

**094493 MAGNETIC, SUSCEPTIBILITY AND SPECIAL FEATURES OF THE STRUCTURAL-CHEMICAL COMPOSITION OF GLASSES OF THE  $\text{As}_2\text{S}_3$ - $\text{AsI}_3$  SYSTEM.** It is established that the concentration dependence of the magnetic susceptibility of glasses of the  $\text{As}_2\text{S}_3$ - $\text{AsI}_3$  system is well explained by a model of the microheterogeneous structure of the glasses. It is shown

that small additions of elements differing with respect to their electronic structure (iodine and iron) lead to the appearance of features of various characters on the concentration dependences of the magnetic susceptibility. In Russian. 14 refs.

Pinzenik, V.P.; Kramarenko, A.N.; Khimnits, V.V.; Rosola, I.I. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 4 Apr 1987 p 654-657.

**094494 ELECTRONIC CONDUCTION IN BASALT GLASS AND GLASS-CERAMICS - CORRELATION WITH MAGNETITE CRYSTALLIZATION.** The dc conductivity measurements have been made in a wide range of temperature on a basalt glass heat-treated at different temperatures to form magnetite particles. Small polaron hopping mechanism is operative in the as-annealed glass between  $\text{Fe}^{2+}$  and  $\text{Fe}^{3+}$  ions in the isolated state. This mechanism is operative in the heat-treated samples between these ions in the magnetite grains. The dc conductivity at 473 K and the activation energy show significant changes around 700°C, when magnetite forms in the basalt glass, which has been correlated with the magnetic data on these samples. TSPC and TSDC data are interesting, but the data analysis is complicated by the possible occurrence of Verwey transition in the small particles of magnetite. Preliminary ac conductivity data support the small polaron hopping mechanism. (Author abstract) 15 refs.

Jurado-Egea, J.R. (Univ of Edinburgh, Edinburgh, Scotl); Owen, A.E.; Bandyopadhyay, A.K. *J Mater Sci* v 22 n 10 Oct 1987 p 3602-3606.

**094495 ELECTRON SPIN RESONANCE IN SOME VANADATE GLASSES.** Interpretation of the semiconductivity in these glasses requires a knowledge of the valency state of the transition metal ions that are present in the glass. The electron spin resonance (e.s.r.) technique provides a useful method for determining the concentration of a paramagnetic species present. The normal ions ( $\text{V}^{5+}$  in vanadate glasses) are diamagnetic hence cannot be detected directly by the e.s.r. technique while the reduced ions  $\text{V}^{4+}$ , which are paramagnetic and have spin  $s = 1/2$ , can be detected directly by e.s.r. leading to a single resonance line influenced by nuclear hyperfine interactions. The combined effect of this interaction and the interaction of adjacent paramagnetic centres results in a line shape which should be characteristic of each glass. 7 refs.

## Mathematical Models

**094496 FREQUENCY-DEPENDENT CONDUCTIVITY IN IONIC GLASSES: A POSSIBLE MODEL.** The frequency-dependent (ac) conductivity behavior of ionically conducting glasses is discussed. A critique is given of the treatment of Almond and West for this behavior. Two models are proposed instead to account for the observed ac loss data. One involves parallel relaxation processes and is a modification of a model originally developed for the case of large-polaron transport in amorphous semiconductors. The other is based on series relaxation, and is based on a model originally proposed by Glarum for the case of dielectric relaxation in molecular liquids. In the development given here, this model is modified so as to describe ionic transport, and a new microscopic transport mechanism is proposed - 'diffusion-controlled relaxation' - which satisfies the requirements of the Glarum theory and which naturally incorporates cooperative ionic motions. For this reason, it is intuitively more appealing. (Author abstract). 54 Refs.

Elliott, S.R. (Univ des Sciences et Techniques de Languedoc, Montpellier, Fr). *Solid State Ionics* v 27 n 3 Jul 1988 p 131-149.

## Optical Properties

**094497 RAMAN SCATTERING STUDY OF LASER INDUCED STRUCTURAL TRANSFORMATIONS IN GLASSY  $\text{As}_2\text{Se}_3$ .** Light induced transformations have been studied as a function of the irradiation time by the Raman scattering technique on the chalcogenide alloy glass  $\text{As}_2\text{Se}_3$ . As a function of the laser intensity we observe: (i) For very low laser intensities there are no detectable changes in the Raman spectra; (ii) For intermediate laser intensities the spectrum exhibits oscillatory changes as a function of the irradiation time; (iii) For high laser intensities crystallization starts after some time of irradiation, which depends on the power level. Our explanations are based on the assumption that the radiation pumps the material from the glassy state towards the crystalline state, through the formation of submicrocrystalline clusters, which can coalesce to form large clusters attaining microcrystalline size at high power levels. (Author abstract) 25 refs.

Abdulhalim, I. (Israel Inst of Technology, Haifa, Isr); Bersman, R. *Solid State Commun* v 64 n 6 Nov 1987 p 951-955.

**094498 OPTICAL ABSORPTION OF VANADIUM IN SODIUM DIBORATE GLASSES.** The optical absorption in blown films and bulk specimens of sodium diborate glasses containing vanadium oxide based on the system  $[\text{Na}_2\text{O}-2\text{B}_2\text{O}_3]_{1-x} [\text{V}_2\text{O}_5]_x$  where  $x=0, 0.05, 0.10, 0.15$  and  $0.20$  has been studied in the wavelength range 200 to 900 nm. The fundamental absorption edge has been analyzed in the light of existing models. Glasses containing a higher content of vanadium have fewer defects compared with those containing a low vanadium content. The absorption spectra are due solely to pentavalent vanadium. (Author abstract) 24 refs.

**094499 EFFECT OF TEMPERATURE ON THE OPTICAL ABSORPTION EDGE OF THE TITANIUM OXIDE-DOPED SODA-LIME SILICA GLASSES.** From the density of states model, the value of  $E_{\text{opt}}$  is decreased as the degree of disorder in the amorphous structure is increased. Also, as temperature increases, the disorder increases and the band tailing shifts to lower energies and extends further into the forbidden band. The absorption index  $K$  is calculated using data of the absorption coefficient ( $\alpha = 4\pi K/\lambda$ ). The results show the variation of this quantity with wavelength for five different temperatures. The increase in absorption index with increasing temperature arises from the higher transition probability of carriers across the smaller optical energy gap. 8 refs.

**094501 PHOTOACOUSTIC STUDIES ON SELENIUM-BASED SEMICONDUCTING GLASSES.** The optical energy gap of amorphous  $\text{Se}_{1-x}\text{Te}_x$  and  $\text{Se}_{1-x}\text{Sb}_x$  semiconducting alloys have been determined as a function of  $x$  using photoacoustic spectroscopy for the first time. The optical energy gap of amorphous selenium reduces drastically on substitution of 2% Sb. On annealing

the optical energy gap of amorphous selenium decreases linearly as a function of annealing temperature towards that of crystalline selenium. (Author abstract) 6 refs.

**094502 PHOTOACOUSTIC STUDIES OF LEAD-VANADATE GLASSES.** Semiconducting lead vanadate glasses ( $\text{V}_2\text{O}_5$ )<sub>x</sub>(PbO)<sub>100-x</sub> glasses have been studied using photoacoustic absorption spectroscopy. It is found that the energy gap  $E_g$  decreases with increasing PbO concentration. Doping of ( $\text{V}_2\text{O}_5$ )<sub>50</sub>(PbO)<sub>50</sub> glass with  $\text{Fe}_2\text{O}_3$  decreases the energy gap, but increase in doping of  $\text{Fe}_2\text{O}_3$  results in the increase of  $E_g$ . ## Physical Properties

**094504  $\text{GeSnSe}_3$  GLASS - A NOVEL EXCEPTION TO THE IOFFE-REGEL RULE.** Glasses based on the  $\text{Ge}_{2-2x}\text{Sn}_{2x}\text{Se}_3$  ternary have been examined using scanning calorimetry, Mossbauer spectroscopy, and molar volume measurements. The origin of extensive glass formation, especially near  $x=0.5$ , is traced to a floppy molecular fragment based on the structure of  $\text{c-GeSnSe}_3$ .  $\text{c-GeSnSe}_3$  does not exist in a structure isomorphous to  $\text{c-GeSnS}_3$ , thus showing  $\text{g-GeSnSe}_3$  to be a novel exception to the Ioffe-Regel Rule. (Author abstract) 15 refs.

Enzweiler, R.N. (Univ of Cincinnati, Cincinnati, OH, USA); Boolchand, P. *Solid State Commun* v 62 n 3 Apr 1987 p 197-200.

**094505 ELASTIC CONSTANTS OF THE CHALCOGENIDES GLASSES ( $\text{Ge}_x\text{Se}_{1-x}$ ,  $\text{As}_y\text{Se}_{1-y}$  AND  $\text{Ge}_{2/3}\text{Se}_{1/3}$ ).** The elastic constants of the three different types of the chalcogenide glasses,  $\text{Ge}_x\text{Se}_{1-x}$  with  $x=0$  to  $0.3$ ,  $\text{As}_y\text{Se}_{1-y}$  with  $y=0$  to  $0.45$ , and  $\text{Ge}_{2/3}\text{As}_{1/3}\text{Se}_{1-z}$  with  $z=0$  to  $0.6$  have been measured. The results are compared with recent theories of the rigidity percolation in covalent networks. Contrary to previous reports, our results do not show any clear anomaly of the elastic constants at the rigidity percolation threshold around the average coordination of 2.4. The origin of the dependence of the anomaly on the experimental methods is discussed. (Edited author abstract) 18 refs.

**094506 EFFECT OF MICROSTRUCTURE AND FUSION TEMPERATURE ON THE ELECTRICAL AND OPTICAL PROPERTIES OF VANADATE GLASSES.** The electrical and optical properties of binary semiconducting oxide glasses containing 45 mol%  $\text{V}_2\text{O}_5$  and 55 mol%  $\text{GeO}_2$  fused and equilibrated at various temperatures ( $T_d$ ) in air were measured.  $T_d$  was varied over the range from 1000 to 1350°C. Their electrical and optical properties are shown to be sensitive to microstruc-

ture and melt temperature. We suggest that the change in  $T_g$  caused progressive microstructure changes of these glasses, which dramatically affected the electronic conductivity and the activation enthalpy for conduction. (Author abstract) 20 refs.

Khan, M.N. (Bahrain Univ, Bahrain). *J Mater Sci* v 23 n 3 Mar 1988 p 847-851.

**094507 OPTICAL ABSORPTION AND THERMAL DIFFUSIVITY IN  $Ge_xTe_{100-x}$  GLASSES BY THE PHOTOACOUSTIC TECHNIQUE.** The variation in the optical energy gap with composition in the  $Ge_xTe_{100-x}$  system ( $15 \leq x \leq 28$ ) of glasses in bulk form has been studied using photoacoustic techniques. It is found that the optical energy gap increases with increasing composition factor  $x$ , with the rate of increase showing a slowing-down trend for compositions with  $x > 20$ . The composition dependence of the thermal diffusivity of these samples has also been measured. The thermal diffusivity is found to peak around the composition corresponding to  $x=20$ . The observed phenomena are explained on the basis of chemical bond formation in this system of glasses. The change in the short-range order and increase in the number of Te-Te bonds with decreasing  $x$  are interpreted as being responsible for the behaviour exhibited by these materials. (Author abstract). 23 Refs.

#### Radiation Effects

**094508 PHOTOINDUCED CHANGES IN THE RATE OF DISSOLUTION OF  $As_2S_3$  AND  $AsSe$  FILMS.** Using the methods of IR spectroscopy and etching kinetics, a study was made of the photo- and thermo-induced changes in the structure of arsenic monoselenide and arsenic sulfide chalcogenide glass films. It was found that the short-range-order structure changes in all the cycles of action on  $AsSe$  films, in contrast to  $As_2S_3$  films, in which structural changes are observed only during irradiation or annealing of fresh films. 6 refs. In Russian.

Mamedov, S.B.; Mikhailov, M.D.; Pogoreva, V.G.; Yakovuk, O.A. *Izv Akad Nauk SSSR Neorg Mater* v 23 n 11 Nov 1987 p 1804-1808.

**094509 STRUCTURAL MODIFICATION OF ARSENIC CHALCOGENIDE GLASSES UNDER  $\gamma$ -RADIATION.** The radiation-induced changes of the molecular structure and properties of chalcogenide glassy semiconductors are analysed. The effect of  $\gamma$ -radiation on the mechanical properties (Young's modules, internal friction) was investigated at various temperatures and radiation doses. At low temperatures the changes of the molecular structure and the corresponding changes of mechanical properties grow with decrease of the structural network rigidity. At higher temperatures the opposite dependence of the properties is found. (Edited author abstract). 8 Refs.

p 507-514.

**094511 APPLICATION OF MOESSBAUER SPECTROSCOPY AND DTA TO A STRUCTURAL STUDY OF SEMICONDUCTING  $P_2O_5-V_2O_5$  GLASSES.** A Moessbauer spectrum series of  $P_2O_5-V_2O_5$  glasses containing 5 mol%  $Fe_2O_3$  consists of a paramagnetic quadrupole doublet, the isomer shift of which varies from 0.37 to 0.32 mm  $s^{-1}$  when the  $P_2O_5$  content is changed from 5 to 40 mol%. This indicates that all the  $Fe^{3+}$  ions are surrounded by four oxygen atoms and that they are present at the substitutional sites of the  $V^{3+}$  or  $V^{4+}$  ions constituting  $VO_4$  tetrahedra. These results are quite different from the Moessbauer result of the  $95V_2O_5 \cdot 5Fe_2O_3$  glass, where the  $Fe^{3+}$  ions prove to be surrounded by six oxygen atoms at the interstitial sites of the layer structure composed of the  $VO_5$  tetragonal pyramids (or trigonal bipyramids). A distinct increase in the quadrupole splitting ranging from 0.71 to 0.90 mm  $s^{-1}$  in the same compositional region indicates an increased electric field gradient at the iron nucleus. (Edited author abstract) 42 refs.

**094512 X-RAY K ABSORPTION EDGES OF Ge AND Se IN  $Ge_{22}Se_{78-x}Bi_x$  GLASSES AND AMORPHOUS FILMS.** The X-ray K absorption edges of Ge and Se in glassy  $Ge_{22}Se_{78-x}Bi_x$  with  $x=0, 2$  and 10 have been studied in bulk as well as in thin-film form. In both cases, we find that, at a low concentration of Bi ( $x=2$ ), the Se K edge shifts while that of Ge remains unchanged. On the other hand, at a higher concentration of Bi ( $x=10$ ), the reverse happens. The results indicate different kinds of bonding at low and high concentrations of Bi. The results are in agreement with those of other workers who drew similar conclusions from the electrical properties. (Author abstract) 14 refs.

Agnihotri, A.K. (Harcourt Butler Technological Inst, Kanpur, India); Kumar, A.; Nigam, A.N. *Philos Mag B* v 57 n 2 Feb 1988 p 319-324.

**094513 PHASE SEPARATION IN  $Ge_{1-x}Sn_xSe_2$  GLASSES.** Raman scattering and Moessbauer spectroscopy have been used to examine the structure of  $Ge_{1-x}Sn_xSe_2$  glasses in the composite range  $0 \leq x \leq 0.7$ . The Raman spectra can be separated into contributions from  $GeSe_2$  and  $SnSe_2$  units, and for  $x \geq 0.35$  a softening of the tetrahedral breathing modes and a shift in the polarizability of the structure are observed. For  $x=0.5$ , thermal annealing results in the precipitation of crystalline  $SnSe_2$ . These results are interpreted to indicate a phase separation of  $GeSe_2$  and  $SnSe_2$  in the amorphous state. (Author abstract) 9 refs.

**094515 X-RAY SPECTROSCOPIC STUDIES OF THE GLASSY  $Ge_{x-1}Se_{100-x}$  SYSTEM.** X-ray K-absorption edges of germanium and selenium have been studied in

glassy  $Ge_xSe_{100-x}$  ( $x = 10, 15, 22$  and 30). We find that the Ge K-absorption edge always shifts towards higher energies with respect to pure amorphous germanium whereas the Se K-absorption edge always shifts towards lower energies with respect to amorphous selenium. In both cases, the shift is found to be a minimum for the particular value  $x = 22$  which indicates some modifications in the structure at this composition. (Author abstract). 17 Refs.

Agnihotri, A.K. (Harcourt Butler Technological Inst, Kanpur, India); Kumar, A.; Nigam, A.N. *Philos Mag Lett* v 58 n 1 Jul 1988 p 63-67.

**094516 XANES AND EXAFS STUDY OF SEMICONDUCTOR GLASSES.** Semiconductor glasses like Se-Te, Te-Ge etc. are characterized by at least a half-filled outer electron shell with the bonding being described by the 8-N rule. These materials are represented by a model of continuous random network of atoms but the short range disorder differs in nature in various systems. This, in turn, influences the shape of density and electron states, in valence and conduction bands, also, it leads to localized electronic states in band tails. XANES and EXAFS techniques offer a very potential method of probing the electronic structure and local ordering as well as changes therein. Being atom specific, they can be tuned to a particular species of atoms present in the system. Of late, EXAFS, the XANES technique has also been showing signs of yielding quantitative data. (Edited author abstract)

#### Structure

**094518 LAYER STRUCTURES IN CHALCOGENIDE GLASSES.** The composition dependence of various properties in chalcogenides glasses shows a transition when the average coordination number is 2.67. A constraint-counting analysis for two-dimensional systems suggests that layer structures are maximally stabilized at the critical composition. (Author abstract). 9 Refs.

Tanaka, Keiji (Hokkaido Univ, Sapporo, Jpn). *J Non Cryst Solids* v 103 n 1 6(II) 1988 p 149-150.

**094519 STRUCTURAL TRANSFORMATION IN N-TYPE Bi DOPED SEMICONDUCTING GLASSES  $Ge_{20}S_{80-x}Bi_x$ .** The problem of controlled doping (n-type/p-type) of amorphous germanium chalcogenides is of great importance due to their application in devices. In this investigation, we have applied techniques of DTA, X-ray diffractometry, electron-microscopy and measurement of electrical transport under high pressure to study the structural features of amorphous Bi doped  $Ge_{20}S_{80-x}Bi_x$  ( $x=0, 4, 11, 15$ ) with a view to understand the mechanism of doping in these semiconductors. The experiments reveal the presence of composite clusters of Ge-S-Bi which decompose into simpler units  $B_2S_3, GeS_2$

on annealing/applying pressure. This indicates the Bi impurity induced chemical modification of the semiconductor. (Author abstract) 6 refs.

Gosain, D.P. (Maharshi Dayananda Univ, Rohtak, India); Bhatia, K.L.; Parthasarathy, G.; Gopal, E.S.R. *Key Eng Mater* v 13 pt 2 1987, Int Conf on Met and Semicond Glasses (MSG-86), Hyderabad, India, Dec 16-20 1986 p 351-354.

**094520 POSITRON ANNIHILATION FOR INVESTIGATION OF CHEMICAL BONDING IN THE STRUCTURES OF As-Se, As-Te AND Ge-Se.** Previous structural studies of Ge-Se, As-Se and As-Te glasses taking traditional techniques revealed some typical structures depending on the glass composition. Thus for the Ge-Se system the tetrahedral units  $\text{GeSe}_{4/2}$  ( $X=30$  at.%Ge) and finally to ethane-like units  $\text{Ge}_2(\text{Se}_2\text{O}_4)_6$  when  $x$  is about 40 at.%. Meanwhile the explanation of the dependence of glass forming temperature and photoluminescence energy on composition for  $\text{As}_x\text{B}_{1-x}$  ( $x > 30$  at.%) using such characteristic as chemical binding energy requires the assumption of existence (along with single Ge-Ge and Ge-Se bonds) of double and triple bonds between germanium (arsenic) atoms. Its validity is proved in this study for As-Se, As-Te and Ge-Se systems using the positron annihilation method. (Author abstract) 7 refs.

## Surfaces

**094521 ELECTRONIC PROCESSED ON THE SURFACE OF As-Se CHALCOGENIDE GLASSY SEMICONDUCTORS.** The paper is a survey of the results obtained in studies of surface processes. As a subject the model glassy semiconductor  $\text{As}_2\text{Se}_3$  was chosen, as well as other compositions in the As-Se system (with deviations from stoichiometry). Glassy  $\text{As}_2\text{Se}_3$  is used to illustrate the major results of these studies. Section 2 is an analysis of experimental data on the effect of mechanical and chemical surface treatment on the properties of glassy  $\text{As}_2\text{Se}_3$ . Section 3 considers the effects associated with adsorption on the surface of  $\text{As}_2\text{Se}_3$  and other compounds of the system. Section 4 sums up the results obtained and discusses the model concepts suggested by these studies. 68 Refs.

## Thermal Effects

**094524 ON THE JOULE SELF-HEATING CURRENT INCREASE CORRESPONDING TO A NON-SWITCHING VOLTAGE IN BULK GLASSY SEMICONDUCTORS.** This paper analyses the influence of Joule self-heating on the electrical conduction process in bulk glassy semiconductors, when non-switching square voltage pulses are applied; the dependence of the heating time constant on the ratio between steady-state current increase and the initial current; and the relationship between steady-state current increase, applied voltage and ambient temperature. (Author abstract) 13 refs.

Marquez, E. (Univ de Cadiz, Cadiz, Spain); Villares, P.; Jimenez-Garay, R. *Semicond Sci Technol* v 3 n 2 Feb 1988 p 161-164.

## Thermal Expansion

**094525 THERMAL EXPANSION OF SOME Ge-Se-Te GLASSES.** Results of measurements of the thermal expansion coefficient (from 50°C to the softening temperature) are reported for eight glass compositions of the Ge-Se-Te system. For  $(\text{GeSe}_2)_{100-2x}\text{Se}_x\text{Te}_x$  glasses, an increase in the glass transition temperature ( $T_g$ ) and in  $\Delta\alpha$  (the change in thermal expansion coefficient,  $\alpha$ , during the glass transition) is seen with decreasing SeTe content. For  $(\text{GeSe}_2)_{23.33}\text{Se}_{30-2x}\text{Te}_x$  glasses,  $\alpha$ ,  $T_g$  and  $\Delta\alpha$  are invariant with composition. These results, when examined along with those obtained for other chalcogenide glasses, indicate that chalcogenide glasses are not necessarily in a stage of isofree volume during glass transition. Values ranging from 0.024 to 0.167 are obtained for the free volume of some chalcogenide glasses. (Edited author abstract) 16 Refs.

## Thermoelectric Effects

**094526 STUDY OF THE ELECTROTHERMAL SWITCHING EFFECT IN BULK GLASSY SEMICONDUCTORS BY A COMPUTER SIMULATION METHOD.** The electrical switching process in glassy semiconductors has been studied by a computer simulation method. The operation of a switching device has been considered from the stand-point of internal heat generation and the attendant rise in device temperature. A simple model has been chosen for an analysis in which the thermal and electrical parameters are related in a nonlinear manner through the exponential dependence of conductivity on temperature. Furthermore, field-dependence effects (space-charge formation) are introduced in order to complete the model, which could be called 'electronically assisted' thermal breakdown. The simulated current-voltage relationship exhibits a turnover voltage and conditions of negative differential resistance. To summarize, it is demonstrated that the application of a computer simulation is useful, in order to examine the switching phenomenon. (Author abstract) 22 refs.

Marquez, E. (Univ de Cadiz, Cadiz, Spain); Villares, P.; Jimenez-Garay, R. *J Mater Sci* v 22 n 12 Dec 1987 p 4434-4438.

## Thin Films

**094527 VIBRATIONAL SPECTROSCOPIC STUDY OF METAL CHALCOGENIDE SPIN-ON-GLASSES.** Thin films of germanium diselenide have been prepared by a spin-on-glass technique from ethylenediamine solutions. The solutions and the films at various

stages of processing have been characterized using infrared and Raman spectroscopies. The results indicate that amorphous  $\text{GeSe}_2$  films are formed after complete processing. At stages prior to the formation of the final film several chemically distinct species are observed. The identification of some of these species offers insight into the formation of solid  $\text{GeSe}_2$  networks. (Author abstract) 20 refs.

Ferris, Nancy S. (Eastman Kodak Co, Rochester, NY, USA); Lelental, Mark. *Mater Res Bull* v 23 n 5 May 1988 p 653-661.

**094528 SILVER PHOTODISSOLUTION AND OPTICAL PROPERTIES OF  $\text{GeSe}_3$  VITREOUS GLASS THIN FILMS.** The photodoping of Ag in thin layers of amorphous  $\text{GeSe}_3$  semiconductors was studied according to the intensity and wavelength of the radiation used. This study is based on the electrical resistance variation of the Ag layer deposited above (or underneath)  $\text{GeSe}_3$  for a given radiation. Optical measurements for wavelengths from 350 nm to 2.5  $\mu\text{m}$  were used to determine the absorption coefficient  $\alpha$  for transparency zones, the index of refraction, and the extinction coefficient of  $\text{GeSe}_3$ . (Author abstract) 45 Refs.

**X-ray Analysis** See Also SEMICONDUCTING GERMANIUM COMPOUNDS—Order-Disorder.

**094529 TOPOLOGICAL FEATURES OF  $\text{Cu}_{15}\text{As}_{34}\text{Se}_{51}$  GLASSY SEMICONDUCTOR.** In a previous work the short-range order of  $\text{Cu}_{15}\text{As}_{34}\text{Se}_{51}$  has been studied by X-ray diffraction from analysis of its radial distribution function (RDF). A conclusion of this work was that the structure is made up of a tetrahedral framework centered on copper atoms, there also being some centered on arsenic atoms. On the basis of short-range order, a 1.07 nm radius spherical model has been built up by a random method. The model is made up of 200 atoms, of which 30 are copper, 70 arsenic, and 100 selenium, if we take into account the material composition. The geometrical fitting of the structure has been carried out by comparison between the RDF of the model and the experimental one, multiplied by a theoretical function, simulating the shape and finite size of the model. 10 refs.

De La Rosa-Fox, N. (Univ De Cadiz, Cadiz, Spain); Esquivias, L. *J Mater Sci Lett* v 7 n 2 Feb 1988 p 105-107.

**094530 STRUCTURAL AND ELECTRICAL PROPERTIES OF THE GLASSY SEMICONDUCTOR SYSTEM Cu-As-Te PART 2 STRUCTURAL ANALYSIS BY X-RAY DIFFRACTION AND SPACE MODELS.** An X-ray diffraction radial distribution study of  $\text{Cu}_{0.05}\text{As}_{0.50}\text{Te}_{0.45}$  and  $\text{Cu}_{0.15}\text{As}_{0.40}\text{Te}_{0.45}$  amorphous alloys obtained by the melt quench method has been performed. The short range order proposed from the radial distribution function (RDF) interpretation was calculated from a theoretical expression that takes into account the variation with  $s$  (scattering vector modulus) of the atomic scattering factor. The local order of both alloys presents a deviation from the covalent character of the arsenic and tellurium elements bound to copper, increasing the mean coordination and not fitting the octet rule. For study of the structural characteristics, tridimensional models were built by computer simulation of an X-ray diffraction experiment. Refinement was carried out by the Metropolis-Monte Carlo method with modifications. The basic structure of both models may be described by a network of tetrahedra centered on copper and arsenic atoms. As both clusters are intermingled, the network connectivity is increased. Both models present a certain number of tellurium atoms with dangling bonds with average bonding distances above the mean value which together with the copper concentration may be responsible for its decreased electrical resistivity. (Author abstract) 24 refs.

Vazquez, J. (Univ de Cadiz, Cadiz, Spain); Marquez, E.; De La Rosa-Fox, N.; Villares, P.; Jimenez-Garay, R. *J Mater Sci* v 23 n 5 May 1988 p 1709-1717.

## SEMICONDUCTING INDIUM

## Electric Conductivity

**094531 ELECTRICAL CONDUCTANCE OF INDIUM THIN FILMS IMMEDIATELY AFTER BEING DEPOSITED.** Several workers have studied the electrical conductance of indium thin films, but little has been reported on the effects on this property due to aging of samples in the form of polycrystalline aggregates. The authors carried out in situ measurements on samples ranging in thickness from 110 to 194 nm. At room temperature, indium films within this thickness range go through a transition from discontinuous (island structure) to continuous films. Electrical resistance measurements as a function of time were made to obtain information on this process. 10 refs.

**094532 EXCITON ABSORPTION AND LUMINESCENCE OF INDIUM SELENIDE CRYSTALS.** By investigations of low-temperature photoluminescence (PL) spectra of InSe crystals the nature of emission lines in the region of indirect exciton transitions is determined and the energy diagram of optical direct and indirect transitions is offered. The pressure in  $\gamma$ -InSe of regions containing stacking faults results in the appearance of a fine structure in the PL spectra of an  $n = 1$  exciton state. Within the framework of a 'resonant exciton' model the causes of the growth of integrated intensity in the absorption spectra of an  $n = 1$  exciton state are discussed. (Author abstract) 18 refs.

**094533 ELECTROCHEMICAL AND SPECTRO-ELECTROCHEMICAL ANALYSIS OF THE OXIDE/p-INDIUM PHOSPHIDE SEMICONDUCTOR SURFACE USING FOURIER TRANSFORM INFRARED AND RAMAN SCATTERING SPECTROSCOPES.** Raman scattering and FTIR reflectance spectroscopies have been used to examine p-InP/oxide surfaces. The thin anodic oxide film grown in pH 6 tartaric acid solutions is found to be primarily indium dihydrogen phosphate. This layer gives rise to an appreciable reduction in band bending (as much as 300 mV) which is similar to that obtained by open circuit photovoltage measurements. The photocurrent-voltage behavior of p-InP/oxide shows that the growth of anodic oxide at p-InP introduces significant surface states which act as surface recombination centers. (Author abstract) 34 refs.

**094534 BAND STRUCTURE OF InN.** The energy band structure of wurtzite-structure semiconductive InN is predicted using empirical nearest-neighbor tight-binding theory. The tight-binding parameters are extrapolated from those of zincblende InP, InAs, and InSb by using empirical rules for the dependences of the parameters on bond length and on row of the Periodic Table. The predicted band gap is direct and agrees well with the data for this potential orange light-emitter. It is suggested that zincblende InN, if it can be grown, also will have a band-gap near 2 eV. (Author abstract) 19 refs.

## Amorphous

**094535 LOW-TEMPERATURE WET-CHEMICAL SYNTHESIS OF AMORPHOUS INDIUM SULFIDE POWDERS.** Indium sulfide is a chalcogenide semiconductor useful in the preparation of green and red phosphors and the manufacture of picture tubes for color television. It was possible to prepare amorphous indium sulfide powders using the reaction between an acidified (pH=1.3) solution of indium chloride and sodium hydrosulfide (NaHS). The indium sulfide powders prepared by this process give a glass transition at 330°C and a crystallization exotherm on heating at 390°C in a DSC. Results of characterization of the amorphous and heat treated powders using electron microscopy (SEM, TEM), electron probe microanalysis (EMPA) and X-ray diffraction (XRD) are presented. (Edited author abstract) 11 refs.

**094536 METAL-SEMICONDUCTOR TRANSITION IN AMORPHOUS InSb FILMS.** The metal-semiconductor transition takes place with the change of the substrate temperature  $T_s$  in amorphous InSb films which is formed by the vapor deposition. Amorphous InSb behaves like a metal for  $T_s > 120$  K, as semiconductor for  $T_s > 120$  K; superconductivity on one side of the metal was investigated. (Edited author abstract) 8 refs.

**094537 INNOVATIVE METHOD FOR PREPARING ANISOTROPIC InSb-NiSb RIBBON.** Amorphous ribbon with InSb-NiSb eutectic composition has been prepared by melt-spinning technique. Subsequent magnetic field annealing above its crystallization temperature caused it to crystallize with parallel aligned NiSb needles in InSb matrix. The effect of heating rate, annealing temperature and field strength on the resulting microstructure and magnetic properties was examined. This new method was shown to be more cost effective than conventional unidirectional eutectic solidification process. The magnetic properties will be compared to those produced by the conventional method. (Author abstract) 3 refs.

**094538 RAMAN SCATTERING BY GaInAs-InP QUANTUM WELLS: EFFECTS OF FREE CARRIERS AND IMPURITIES.** We report a Raman scattering study of the effects of free carriers, produced by both photo-excitation and remote doping, on the LO phonons in both bulk  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As}$  and  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As-InP}$  single quantum wells. In the bulk alloy high carrier densities cause both a weakening and a shift to lower energy of the dominant GaAs-like LO phonon. In the quantum-well structures this effect is greatly enhanced due to the efficient trapping of photo-excited carriers in the well. This behavior is in contrast to that of the InP capping layer where we observe a coupled LO-plasmon mode on the high-energy side of the LO phonon. Removal of the InP capping layer by selective etching allows us to study effects of this layer on the  $\text{Ga}_{0.47}\text{In}_{0.53}\text{As}$  phonons. In addition, the quantum-well Raman spectra indicate the presence of impurities due to cross contamination during growth. (Author abstract) 21 refs.

**094539 SUBBAND STRUCTURE CALCULATION FOR INVERSION LAYERS IN InAs AND InP.** The complete electronic subband structure of n-inversion layers of InAs- and InP-MIS systems is calculated using a new approximate self-consistent method. Remarkable agreement with recently published experimental results is obtained if the non-parabolicity of the conduction band is taken into account. Landau levels are calculated also for InP accounting for the non-parabolicity. (Author abstract) 12 refs.
